ALGORITHMS FOR FUSION SYSTEMS WITH APPLICATIONS TO *p*-GROUPS OF SMALL ORDER

CHRIS PARKER AND JASON SEMERARO

ABSTRACT. For a prime p, we describe a protocol for handling a specific type of fusion system on a p-group by computer. These fusion systems contain all saturated fusion systems. This framework allows us to computationally determine whether or not two subgroups are conjugate in the fusion system for example. We describe a generation procedure for automizers of every subgroup of the p-group. This allows a computational check of saturation. These procedures have been implemented using MAGMA [BCP97]. We describe a computer program which searches for saturated fusion systems \mathcal{F} on p-groups with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. Employing these computational methods we determine all such fusion systems on groups of order p^n where $(p, n) \in \{(3, 4), (3, 5), (3, 6), (3, 7), (5, 4), (5, 5), (5, 6), (7, 4), (7, 5)\}$. This gives the first complete picture of which groups can support saturated fusion systems with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$ on small p-groups of odd order.

1. INTRODUCTION

Our primary goal is to address questions raised in [AKO11, Open Problem 4, page 217] and so to develop a deeper understanding of saturated fusion systems on *p*-groups of odd order. With this in mind, we give a computational framework in which to perform calculations with a certain special type of fusion system which contains the class of all saturated fusion systems. In particular, we describe an implementation of algorithms which check saturation of such fusion systems. Our main contribution is an explicit description of an algorithm to determine all saturated fusion systems \mathcal{F} on a given *p*-group for any prime *p*. Exploiting the library of small groups available in the MAGMA system [BCP97], we use our implementation to create a complete list of saturated fusion systems \mathcal{F} with $O_p(\mathcal{F}) = 1$ and $\mathcal{F} = O^p(\mathcal{F})$ on small *p*-groups of odd order.

Main Result. For all $(p, n) \in \{(3, 4), (3, 5), (3, 6), (3, 7), (5, 4), (5, 5), (5, 6), (7, 4), (7, 5)\}$, all saturated fusion systems \mathcal{F} with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$ on p-groups of order p^n are determined and listed in Appendix A.

Further details of the saturated fusion systems which appear are given in Theorems 5.1, 5.2, 5.5 and 5.7, and a forensic look at each of them is provided in Appendix A. An analogous result for 2-groups of order at most 2^9 was obtained recently by Andersen, Oliver and Ventura in [AOV17]. We recover their classification for groups of order at most 2^8 via an automated approach (see Theorem 5.9). In Section 6, we present a number of general results and conjectures motivated by examining the fusion systems that our programs output. This begins to address the questions raised by Oliver as described above.

As recalled in Section 2, a saturated fusion system \mathcal{F} on a finite *p*-group *S* is a category whose objects are the subgroups of *S*, and whose morphisms are group homomorphisms which are indistinguishable from those coming from conjugacy relations in a finite group in which *S* is a Sylow *p*-subgroup. We wish to encode fusion systems, and our method for doing so begins with the Alperin-Goldschmidt Theorem (Theorem 2.4) which asserts that a saturated fusion system \mathcal{F} is completely determined by $\operatorname{Aut}_{\mathcal{F}}(S)$ and the \mathcal{F} -automorphisms of certain so-called \mathcal{F} -essential

²⁰¹⁰ Mathematics Subject Classification. 20D20, 20D05.

subgroups. For this reason, we propose that a certain family of fusion systems should be computationally understood in terms of a *fusion datum* on S which is simply a collection \mathcal{Q} of subgroups of S (including S itself), together with a map A which assigns a group of automorphisms to each member of \mathcal{Q} . To a fusion datum $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ on S we associate the unique minimal fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$ on S in which $\mathcal{A}(Q) \leq \operatorname{Aut}_{\mathcal{F}}(Q)$ for all $Q \in \mathcal{Q}$. In order to calculate with \mathcal{F} algorithmically, we associate a combinatorial object $\Gamma(\mathcal{D})$ to \mathcal{D} called its *fusion graph*. Our first main result, Theorem 3.9, demonstrates that we can use the fusion graph to read off whether subgroups of S are \mathcal{F} -conjugate and to calculate Aut_F(P) for each $P \leq S$. The proof of Theorem 3.9 is constructive so that the calculation of $\operatorname{Aut}_{\mathcal{F}}(P)$ from \mathcal{D} can be implemented. In particular, we can calculate Aut_F(Q), and the condition $\mathcal{A}(Q) = \operatorname{Aut}_F(Q)$ forms part of the definition of an *automizer* sequence which is a fusion datum in which elements of \mathcal{Q} resemble essential subgroups in a saturated fusion system. More precisely, by the Alperin-Goldschmidt Theorem, every saturated fusion system determines an automizer sequence in which Q is a set of \mathcal{F} -conjugacy class representatives of \mathcal{F} -essential subgroups. All that remains, therefore, is to determine which automizer sequences give rise to saturated fusion systems. We achieve this by checking the surjectivity property holds for fully \mathcal{F} -normalized \mathcal{F} -conjugacy class representatives of \mathcal{F} -centric subgroups.

In Section 4 we describe our algorithm to determine saturated fusion systems on a small group S. We begin by identifying various group theoretic properties of S and its subgroups which preclude S from supporting a saturated fusion system \mathcal{F} which has \mathcal{F} -essential subgroups. Some of the theorems we cite rely on the classification of finite simple groups. For example, we choose to use the structure of Sylow p-subgroups of groups with a strongly p-embedded subgroup. Though such results are not strictly necessary for the algorithms, they do speed up our procedures. We apply these results to severely restrict the list of small groups of order p^n which require more intensive computation. For any group S which cannot be ruled out with the initial tests, we produce a list \mathcal{P}_S of S-conjugacy class representatives of subgroups of S which are potentially \mathcal{F} -essential in some saturated fusion system on S. The next step determines the possibilities for $\operatorname{Out}_{\mathcal{F}}(S)$. Roughly, for each $\operatorname{Out}(S)$ -conjugacy class representative $B_0 \leq \operatorname{Out}(S)$ and each subset \mathcal{Q} of \mathcal{P}_S we describe an algorithm to list all automizer sequences $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ on S in which $\operatorname{Out}_{\mathcal{F}(\mathcal{D})}(S) = B_0$. We determine saturation by means of the procedure outlined above.

In Section 5 we summarise the results of our computations. In his thesis [Mon18] Moragues Moncho determines all simple saturated fusion systems on groups of order p^4 and our results are consistent with his calculations. When $p \ge 5$ the list of simple saturated fusion systems on groups of order p^5 can be classified using results of Grazian [Gra18] (see Corollary 5.3). We complete this classification with an examination of the case p = 3.

Many of the examples which appear in the paper are saturated fusion systems on groups of maximal class. We follow Blackburn's notation and give a description of these presentations in Appendix A. This allows us to describe various subgroups explicitly and so as well as using the SmallGroup notation in MAGMA we also identify these groups using Blackburn's notation which carries more structural information. We hope that this will provoke conjectures concerning the groups of maximal class which support saturated fusion systems \mathcal{F} in which $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. For example, in Conjecture 1 we make a speculation about which Blackburn groups of order p^6 support such fusion systems.

In Theorem 5.7 we show that, of the 9310 groups of order 3^7 , remarkably only 8 support a saturated fusion system \mathcal{F} in which $O^3(\mathcal{F}) = \mathcal{F}$ and $O_3(\mathcal{F}) = 1$. Of those, 3 are direct products and 2 are Sylow 3-subgroups of sporadic simple groups.

We complete the introduction with a list of basic functions which have been implemented in MAGMA using the approach outlined above; some of these functions are discussed in more detail in Section 3. The package of MAGMA functions can be found at [PS20].

Let p be a prime, S be a finite p-group, \mathcal{F} and \mathcal{G} be fusion systems on S (understood in terms of fusion data), P and R be subgroups of S and G be a finite group.

$$\begin{split} & \text{IsIsomorphic}(\mathsf{F},\mathsf{G}): \quad \text{returns true iff } \mathcal{F} \text{ and } \mathcal{G} \text{ are isomorphic} \\ & \text{GroupFusionSystem}(\mathsf{G},\mathsf{p}): \quad \text{returns the } p\text{-fusion system associated to the group } G \\ & \text{IsConjugate}(\mathsf{F},\mathsf{P},\mathsf{R}): \quad \text{returns true iff } P \text{ and } R \text{ are } \mathcal{F}\text{-conjugate} \\ & \text{IsFullyNormalized}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is fully } \mathcal{F}\text{-normalized} \\ & \text{IsFullyAutomized}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is fully } \mathcal{F}\text{-automized} \\ & \text{IsFullyCentralized}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is fully } \mathcal{F}\text{-centralized} \\ & \text{IsCentric}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is fully } \mathcal{F}\text{-centralized} \\ & \text{IsCentric}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is fully structure iff } \mathcal{F} \text{ is saturated} \\ & \text{SurjectivityProperty}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ has the surjectivity property in } \mathcal{F} \\ & \text{IsSaturated}(\mathsf{F}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{Core}(\mathsf{F}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{Core}(\mathsf{F}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{SurjectivityProperty}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{Core}(\mathsf{F}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{Core}(\mathsf{F}): \quad \text{returns true iff } \mathcal{F} \text{ is saturated} \\ & \text{Surjective}(\mathcal{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is weakly } \mathcal{F}\text{-closed} \\ & \text{IsStronglyClosed}(\mathsf{F},\mathsf{P}): \quad \text{returns true iff } P \text{ is strongly } \mathcal{F}\text{-closed} \\ & \text{AllFusionSystems}(\mathsf{S}): \quad \text{lists all saturated } \mathcal{F} \text{ on } S \text{ with } O^p(\mathcal{F}) = \mathcal{F} \text{ and } O_p(\mathcal{F}) = 1 \\ & \text{IsStronglyClosed}(\mathsf{F},\mathsf{P}): \\ & \text{Issteal} \text{ saturated } \mathcal{F} \text{ on } S \text{ with } O^p(\mathcal{F}) = \mathcal{F} \text{ and } O_p(\mathcal{F}) = 1 \\ & \text{Issteal} \text{ saturated } \mathcal{F} \text{ on } S \text{ with } O^p(\mathcal{F}) = \mathcal{F} \text{ and } O_p(\mathcal{F}) = 1 \\ & \text{Issteal} \text{ saturated } \mathcal{F} \text{ on } S \text{ with } O^p(\mathcal{F}) = \mathcal{F} \text{ and } O_p(\mathcal{F}) = 1 \\ & \text{Issteal} \text{ saturated } \mathcal{F} \text{ on } S \text{ with } O^p(\mathcal{F}) = \mathcal{F} \text{ and } O_p(\mathcal{F}) = 1 \\ & \text{Issteal} \mathcal{F} \text{ or } S \text{ with$$

There are additional parameters which can be added to AllFusionSystems(S) which allow it to calculate saturated fusion systems on S with $O_p(\mathcal{F}) \neq 1$ or $O^p(\mathcal{F}) \neq \mathcal{F}$.

Acknowledgements. We thank David Craven for giving us access to computational resources provided by the Royal Society. We also thank the referees for a careful reading of our original manuscript, for suggesting improvements to both the text and the proofs and for pointing out various inaccuracies.

2. Background

Let p be a prime, and S be a finite p-group. If $P, Q \leq S$ and G is a group with $S \leq G$ define

$$N_G(P,Q) = \{g \in G \mid P^g \leq Q\}$$
 and $\operatorname{Hom}_G(P,Q) = \{c_g \mid g \in N_G(P,Q)\},\$

where c_g is the conjugation map induced by g given by $c_g : x \mapsto g^{-1}xg$. We have $\operatorname{Hom}_G(P,Q) \subseteq \operatorname{Inj}(P,Q)$, where $\operatorname{Inj}(P,Q)$ is the set of all injective group homomorphisms from P to Q. A fusion system or p-fusion system \mathcal{F} on S is a category whose objects are the set of subgroups of S and, for all objects $P, Q \leq S$, the morphisms from P to Q, $\operatorname{Mor}_{\mathcal{F}}(P,Q)$, have the following two properties

- (1) $\operatorname{Hom}_{S}(P,Q) \subseteq \operatorname{Mor}_{\mathcal{F}}(P,Q) \subseteq \operatorname{Inj}(P,Q);$
- (2) every morphism $\varphi \in \operatorname{Mor}_{\mathcal{F}}(P,Q)$ factorizes as an \mathcal{F} -isomorphism $P \to P\varphi$ followed by an inclusion $P\varphi \hookrightarrow Q$.

We write $\operatorname{Hom}_{\mathcal{F}}(P,Q)$ in place of $\operatorname{Mor}_{\mathcal{F}}(P,Q)$. The universal fusion system on S is denoted by \mathcal{U} and defined by setting $\operatorname{Hom}_{\mathcal{U}}(P,Q) = \operatorname{Inj}(P,Q)$. If G is a group with $S \leq G$, we write $\mathcal{F}_S(G) \subseteq \mathcal{U}$ for the fusion system on S defined by

$$\operatorname{Hom}_{\mathcal{F}_S(G)}(P,Q) = \operatorname{Hom}_G(P,Q).$$

Moreover, we write \mathcal{U}^G for the set of all subfusion systems of \mathcal{U} containing $\mathcal{F}_S(G)$. By (1) above \mathcal{U}^S is the set of all fusion systems on S, and it is a fact due to Park [Par16] that the map $\mathcal{F}_S(-)$ which sends finite groups containing S to \mathcal{U}^S is surjective. Our framework for calculating fusion systems on a group T, first maps T to a standard copy S of T where all the fusion systems on S are constructed and so all fusion systems on T can be transported into \mathcal{U}^S .

If $\mathcal{F} \in \mathcal{U}^S$ and $\theta \in \operatorname{Aut}(S)$, then we define \mathcal{F}^{θ} to be the fusion system in \mathcal{U}^S defined by

$$\operatorname{Hom}_{\mathcal{F}^{\theta}}(P,Q) = \{\theta^{-1}\gamma\theta \mid \gamma \in \operatorname{Hom}_{\mathcal{F}}(P\theta^{-1},Q\theta^{-1})\}.$$

If $\mathcal{G} \in \mathcal{U}^S$, we say that \mathcal{F} is *isomorphic* to \mathcal{G} and write $\mathcal{F} \cong \mathcal{G}$ if there exists $\theta \in \operatorname{Aut}(S)$ such that $\mathcal{G} = \mathcal{F}^{\theta}$. Thus $\operatorname{Aut}(S)$ partitions \mathcal{U}^S into *isomorphism classes* of fusion systems.

We next consider generation of fusion systems. Following [AKO11, Definition I.3.4(b)], if \mathcal{X} is a set of monomorphisms between subgroups of S and/or fusion systems over subgroups of S, the fusion system generated by \mathcal{X} is denoted $\langle \mathcal{X} \rangle$ and defined to be the smallest fusion system on Swhose morphism set contains \mathcal{X} . Equivalently,

$$\langle \mathcal{X}
angle = igcap_{\mathcal{G} \in \mathcal{U}^S, \mathcal{X} \subset \operatorname{Hom}(\mathcal{G})} \mathcal{G}$$

The morphisms in $\langle \mathcal{X} \rangle$ are composites of restrictions of homomorphisms in $\mathcal{X} \cup \text{Inn}(S)$. Note that $\langle X \rangle^{\alpha} = \langle X^{\alpha} \rangle$ for all $\alpha \in \text{Aut}(S)$.

With the above terminology in mind, we now introduce the class of fusion systems on which we focus all our attention: those which are saturated. If \mathcal{F} is a fusion system on S and $P \subseteq S$, we write

$$P^{\mathcal{F}} = \{ P\alpha \mid \alpha \in \operatorname{Hom}_{\mathcal{F}}(P, S) \}$$

for the set of all images of P under morphisms in \mathcal{F} and call this the \mathcal{F} -conjugacy class of P. For $g \in S$, we write $g^{\mathcal{F}}$ rather than $\{g\}^{\mathcal{F}}$.

Definition 2.1. Let \mathcal{F} be a fusion system on a finite *p*-group *S* and *P*, $Q \leq S$. Then,

- (1) P is fully \mathcal{F} -normalized provided $|N_S(P)| \geq |N_S(Q)|$ for all $Q \in P^{\mathcal{F}}$;
- (2) P is fully \mathcal{F} -centralized provided $|C_S(P)| \ge |C_S(Q)|$ for all $Q \in \mathcal{P}^{\mathcal{F}}$;
- (3) P is fully \mathcal{F} -automized provided $\operatorname{Aut}_{S}(P) \in \operatorname{Syl}_{p}(\operatorname{Aut}_{\mathcal{F}}(P));$
- (4) P is S-centric if $C_S(P) = Z(P)$, and \mathcal{F} -centric if Q is centric for all $Q \in P^{\mathcal{F}}$;
- (5) P is \mathcal{F} -essential if P < S, P is \mathcal{F} -centric, fully \mathcal{F} -normalized and $\operatorname{Out}_{\mathcal{F}}(P)$ contains a strongly p-embedded subgroup; write $\mathcal{E}_{\mathcal{F}}$ to denote the set of \mathcal{F} -essential subgroups of \mathcal{F} ;
- (6) P is weakly \mathcal{F} -closed if $P\alpha = P$ for all $\alpha \in \operatorname{Hom}_{\mathcal{F}}(P, S)$;
- (7) P is strongly \mathcal{F} -closed if for each $g \in P, g^{\mathcal{F}} \subseteq P$;
- (8) if $\alpha \in \operatorname{Hom}_{\mathcal{F}}(P,Q)$ is an isomorphism,

$$N_{\alpha} = \{g \in N_S(P) \mid \alpha^{-1}c_g \alpha \in \operatorname{Aut}_S(Q)\}$$

is the α -extension control subgroup of S;

- (9) Q is \mathcal{F} -receptive provided for all isomorphisms $\alpha \in \operatorname{Hom}_{\mathcal{F}}(P,Q)$, there exists $\widetilde{\alpha} \in \operatorname{Hom}_{\mathcal{F}}(N_{\alpha},S)$ such that $\widetilde{\alpha}|_{P} = \alpha$;
- (10) P is \mathcal{F} -saturated provided there exists $Q \in P^{\mathcal{F}}$ such that Q is simultaneously
 - (a) fully \mathcal{F} -automized; and
 - (b) \mathcal{F} -receptive;
- (11) \mathcal{F} is *saturated* if every subgroup of S is \mathcal{F} -saturated.

If G is a finite group containing S as a Sylow p-subgroup then $\mathcal{F}_S(G)$ is a saturated fusion system. A saturated fusion system \mathcal{F} on S is *realizable* if $\mathcal{F} = \mathcal{F}_S(G)$ for such a group G, otherwise \mathcal{F} is *exotic*.

We now turn to the problem of demonstrating that a fusion system is saturated. The following property may be regarded a modification of \mathcal{F} -receptivity:

Definition 2.2. Let \mathcal{F} be a fusion system on S. $P \leq S$ has the \mathcal{F} -surjectivity property if for each $C_S(P)P \leq R \leq N_S(P)$,

$$N_{\operatorname{Aut}_{\mathcal{F}}(R)}(P) \to N_{\operatorname{Aut}_{\mathcal{F}}(P)}(\operatorname{Aut}_{R}(P))$$

is surjective.

Here is the main computational tool we use when proving saturation:

Theorem 2.3. Let \mathcal{F} be a fusion system on S. Then \mathcal{F} is saturated if and only if the following conditions hold:

- (1) S is fully \mathcal{F} -automized;
- in every F-conjugacy class of F-centric subgroups there is a fully F-normalized subgroup with the F-surjectivity property;
- (3) $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(P) \mid P \text{ is } \mathcal{F}\text{-centric } \rangle.$

Proof. See [Cra11, Lemma 6.6, Theorem 6.16].

Most of our calculations will work with $\operatorname{Aut}_{\mathcal{F}}(S)$ -conjugacy classes of subgroups of S. Note that if P is fully \mathcal{F} -normalized and has the surjectivity property then the same is true of $P\beta$ for all $\beta \in \operatorname{Aut}_{\mathcal{F}}(S)$. This means that it is enough to check Theorem 2.3 (2) for a single $\operatorname{Aut}_{\mathcal{F}}(S)$ -conjugacy class representative within each \mathcal{F} -conjugacy class.

In order to restrict the class of subgroups we apply the following result which may be regarded as a strengthening of the 'only if' direction of Theorem 2.3:

Theorem 2.4 (Alperin-Goldschmidt). If \mathcal{F} is saturated then $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{E}_{\mathcal{F}} \rangle$. *Proof.* See [AKO11, Theorem I.3.5].

If some subset \mathcal{E} of the set of subgroups of S has the property that $\{\operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{E}\}$ generates \mathcal{F} then the same is true of any set of \mathcal{F} -conjugacy class representatives of elements of \mathcal{E} :

Lemma 2.5. Let \mathcal{E} be a set of subgroups of S such that $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{E} \rangle$. Let $\mathcal{E}^{\circ} \subseteq \mathcal{E}$ be a set of \mathcal{F} -conjugacy class representatives. Then $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{E}^{\circ} \rangle$.

Proof. See [Cra11, Proposition 7.25].

We close this section with some additional definitions pertaining to the normal structure of a saturated fusion system \mathcal{F} on S. We denote by $O_p(\mathcal{F})$ the largest subgroup of S which is left invariant by all morphisms in \mathcal{F} . A basic fact concerning this subgroup is that $O_p(\mathcal{F})$ is contained in every member of $\mathcal{E}_{\mathcal{F}}$ (see [Cra11, Theorem 5.39]). The smallest normal subsystem of \mathcal{F} of index prime to p is denoted $O^{p'}(\mathcal{F})$ (see [AKO11, Section I.6].) Finally recall from [AKO11, Section I.7] that

$$\begin{aligned} & \mathfrak{foc}(\mathcal{F}) &:= \langle g^{-1}(g\alpha) \mid g \in P \leq S \text{ and } \alpha \in \operatorname{Aut}_{\mathcal{F}}(P) \rangle; \\ & \mathfrak{hyp}(\mathcal{F}) &:= \langle g^{-1}(g\alpha) \mid g \in P \leq S \text{ and } \alpha \in O^p(\operatorname{Aut}_{\mathcal{F}}(P)) \rangle, \end{aligned}$$

and that a subsystem \mathcal{E} of \mathcal{F} has *p*-power index in \mathcal{F} if $T \geq \mathfrak{hyp}(\mathcal{F})$ and $\operatorname{Aut}_{\mathcal{E}}(P) \geq O^p(\operatorname{Aut}_{\mathcal{F}}(P))$ for each $T \leq S$. If \mathcal{F} is saturated then there is a unique minimal saturated fusion system on $\mathfrak{hyp}(\mathcal{F})$ which is normal in \mathcal{F} which we denote by $O^p(\mathcal{F})$ ([AKO11, Theorem I.7.4]). A saturated fusion system \mathcal{F} is reduced if and only if $\mathcal{F} = O^p(\mathcal{F}) = O^{p'}(\mathcal{F})$ and $O_p(\mathcal{F}) = 1$. We need the following two facts:

Lemma 2.6. Let \mathcal{F} be a saturated fusion system on S. The following hold:

(1)
$$\mathfrak{foc}(\mathcal{F}) = \langle g^{-1}(g\alpha) \mid g \in Q \leq S, Q \text{ is } \mathcal{F}\text{-essential or } Q = S, \alpha \in \operatorname{Aut}_{\mathcal{F}}(Q) \rangle.$$

(2) $O^p(\mathcal{F}) = \mathcal{F}$ if and only if $\mathfrak{foc}(\mathcal{F}) = \mathfrak{hyp}(\mathcal{F}) = S$.

Proof. (1) is an immediate consequence of Theorem 2.4 while (2) follows from [AKO11, Corollary I.7.5]. \Box

3. The fusion graph and automizer sequences

In what follows, we assume S is a fixed finite p-group. We think of this as a fixed post: if we have a fusion system on a group isomorphic to S, we move it by an isomorphism to be a fusion system in \mathcal{U}^S and we consider S as our fixed representative of all finite groups isomorphic to S.

Definition 3.1. A fusion datum \mathcal{D} on S is a pair $(\mathcal{Q}, \mathcal{A})$, where:

- (1) \mathcal{Q} is a sequence of S-centric subgroups of S whose first element is S;
- (2) \mathcal{A} is a map which associates to each $Q \in \mathcal{Q}$ a subgroup $\mathcal{A}(Q) \leq \operatorname{Aut}(Q)$ which contains $\operatorname{Aut}_{S}(Q)$.
- (3) no two members of \mathcal{Q} are in the same $\mathcal{A}(S)$ -orbit.

We write $\mathcal{F}(\mathcal{D}) := \langle \mathcal{A}(Q) | Q \in \mathcal{Q} \rangle$ for the smallest fusion system on S containing each $\mathcal{A}(Q)$.

By Theorem 2.4, every saturated fusion system is given by a fusion datum on S. However it is not the case that every fusion system on S arises in this way. For example, if $S = \langle s, t \rangle$ is elementary abelian of order 4, we can define a fusion system \mathcal{G} which has all the inclusion maps evident in $\mathcal{F}_S(S)$ and is then determined by $\operatorname{Aut}_{\mathcal{G}}(X) = 1$ for all $X \leq S$, $\operatorname{Hom}_{\mathcal{G}}(\langle s \rangle, \langle st \rangle) = \emptyset = \operatorname{Hom}_{\mathcal{G}}(\langle t \rangle, \langle st \rangle)$ and $\theta : s \mapsto t$ the unique element of $\operatorname{Hom}_{\mathcal{G}}(\langle s \rangle, \langle t \rangle)$.

Finally, note that, if $\mathcal{F} = \mathcal{F}(\mathcal{D})$ arises from some fusion datum \mathcal{D} , we have $\mathcal{A}(Q) \leq \operatorname{Aut}_{\mathcal{F}}(Q)$ for each $Q \in \mathcal{Q}$ but there is no guarantee that equality holds. We will return to this point shortly.

Definition 3.2. The fusion data $\mathcal{D}_1 = (\mathcal{Q}_1, \mathcal{A}_1)$ and $\mathcal{D}_2 = (\mathcal{Q}_2, \mathcal{A}_2)$ on S are *isomorphic* if and only if there exists $\theta \in \operatorname{Aut}(S)$ such that

$$\mathcal{Q}_2 = \{ Q\theta \mid Q \in \mathcal{Q}_1 \}$$

and, for $Q \in \mathcal{Q}_1$,

$$\mathcal{A}_2(Q\theta) = \mathcal{A}_1(Q)^{\theta} \le \operatorname{Aut}(Q\theta).$$

The following lemma is immediate:

Lemma 3.3. Suppose that \mathcal{D}_1 and \mathcal{D}_2 are isomorphic fusion data on S. Then $\mathcal{F}(\mathcal{D}_1)$ and $\mathcal{F}(\mathcal{D}_2)$ are isomorphic.

We emphasise that two different fusion data on a group S can have equal fusion systems.

Given a fusion datum $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$, we let S/\mathcal{D} denote a fixed set of $\mathcal{A}(S)$ -orbit representatives of all subgroups of S chosen so that each $Q \in \mathcal{Q}$ is contained in S/\mathcal{D} . For $X \leq S$, let [X] be the $\mathcal{A}(S)$ -orbit representative of X in S/\mathcal{D} .

Definition 3.4. Suppose that $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ is a fusion datum on S. The fusion graph of \mathcal{D} is a graph $\Gamma(\mathcal{D})$ whose vertices are elements of S/\mathcal{D} and edges are defined to be the 2-element sets $\{R, T\} \subseteq S/\mathcal{D}$ such that there exist $\alpha, \gamma \in \mathcal{A}(S), Q \in \mathcal{Q}$ and $\beta \in \mathcal{A}(Q)$ such that $R\alpha, T\gamma \leq Q$ and $R\alpha\beta = T\gamma$.

Given a fusion datum \mathcal{D} , $\Gamma(\mathcal{D})$ is a finite graph. For each edge $\{R, T\}$ in the undirected graph $\Gamma(\mathcal{D})$, we temporarily choose an arbitrary orientation [R, T]. Since $\{R, T\}$ is an edge, there exists $Q \in \mathcal{Q}, \alpha, \gamma \in \mathcal{A}(S)$ and $\beta \in \mathcal{A}(Q)$ such that $R\alpha\beta\gamma^{-1} = T$ and $T\gamma\beta^{-1}\alpha^{-1} = R$. We set $\Theta_{R,T} = \alpha\beta\gamma^{-1}$ and $\Theta_{T,R} = \Theta_{R,T}^{-1}$ and label $\{R, T\}$ with the pair $[\Theta_{R,T}, \Theta_{T,R}]$. Clearly $\Gamma(\mathcal{D})$ is uniquely determined up to isomorphism by \mathcal{D} whereas typically there will be many different labels for the edges of $\Gamma(\mathcal{D})$. Given $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ and $\mathcal{F} = \mathcal{F}(\mathcal{D})$, we can encode Definition 3.4 in order to produce a function LabelledFusionGraph(F) which has as input $\mathcal{F} = \mathcal{F}(\mathcal{D})$ and outputs the graph $\Gamma(\mathcal{D})$ and a set of labels, which are not necessarily well-defined but are stored and fixed once and for all.

Lemma 3.5. Assume that \mathcal{D} is a fusion datum and set $\mathcal{F} = \mathcal{F}(\mathcal{D})$.

- (1) If X, Y are vertices in $\Gamma(\mathcal{D})$ and $\{X = X_0, X_1\}, \{X_1, X_2\}, \dots, \{X_{k-1}, X_k = Y\}$ is a path connecting X to Y in $\Gamma(\mathcal{D})$, then $\prod_{i=0}^k \Theta_{X_i, X_{i+1}} \in \operatorname{Hom}_{\mathcal{F}}(X, Y)$.
- (2) If $X', Y' \leq S$ are \mathcal{F} -conjugate and $\alpha, \beta \in \mathcal{A}(S)$ are such that $X'\alpha = X$ and $Y'\beta = Y$ for some $X, Y \in S/\mathcal{D}$, then X and Y are in the same connected component of $\Gamma(\mathcal{D})$.

For distinct $X, Y \in S/\mathcal{D}$ in the same connected component of $\Gamma(\mathcal{D})$, we temporarily choose an arbitrary orientation [X, Y] and label $\{X, Y\}$ with the pair $[\Theta_{X,Y}, \Theta_{Y,X}]$ where $\Theta_{X,Y}$ is the element of $\operatorname{Hom}_{\mathcal{F}}(X, Y)$ given by Lemma 3.5(1) and $\Theta_{Y,X} := \Theta_{X,Y}^{-1}$.

Next we explain how, using $\Gamma(\mathcal{D})$, one can calculate $\operatorname{Aut}_{\mathcal{F}}(P)$ for $P \leq S$. By replacing P by a suitable $\mathcal{A}(S)$ -conjugate if necessary we may assume that P is a vertex of $\Gamma(\mathcal{D})$. Let $\Gamma(P)$ be the connected component of $\Gamma(\mathcal{D})$ containing the vertex P and notice that

$$P^{\mathcal{F}} = \{ X\beta \mid X \in \Gamma(P), \beta \in \mathcal{A}(S) \}$$

For $X \in P^{\mathcal{F}}$, we define $\Theta_{X,X}$ to be the identity map. For $X', Y' \in P^{\mathcal{F}}$ with $X' \neq Y'$ we select $\beta, \delta \in \mathcal{A}(S)$ such that $X' = X\beta$ and $Y' = Y\delta$ with $X, Y \in S/\mathcal{D}$ and specify

$$\Theta_{X',Y'} = \beta^{-1} \Theta_{X,Y} \delta$$
 and $\Theta_{Y',X'} = \Theta_{X',Y'}^{-1}$

It will be inconsequential that these assignments are not well-defined. The objective is to provide an element of $\operatorname{Hom}_{\mathcal{F}}(X,Y)$ for each $X, Y \in P^{\mathcal{F}}$.

By construction, $\Theta_{Y,X} = \Theta_{X,Y}^{-1}$. For a pair of subgroups $X, Y \in S/\mathcal{D}$, and indeed for subgroups $X, Y \leq S$, by the above discussion we can compute and hence also implement IsConjugate(F,X,Y), IsCentric(F,X), IsFullyNormalized(F,X), IsFullyCentralized(F,X). Furthermore, if IsConjugate(F,X,Y) outputs true, it also outputs an element $\theta \in \text{Hom}_{\mathcal{F}}(X,Y)$.

For each $T \in P^{\mathcal{F}}$, define

$$\mathcal{Q}^{\geq T} = \{ Q \in \mathcal{Q} \mid T \leq Q \}.$$

We set

$$C_T = \langle \Theta_{T,T\mu}(\mu|_{T\mu})^{-1} \mid \mu \in \mathcal{A}(Q), Q \in \mathcal{Q}^{\geq T} \rangle$$

and then put

$$B_P = \langle \Theta_{P,T} \psi \Theta_{T,P} \mid \psi \in C_T \text{ and } T \in P^{\mathcal{F}} \rangle.$$

Finally define

$$A_P = \langle B_P, \Theta_{P,R} \Theta_{R,T} \Theta_{T,P} \mid R, T \in P^{\mathcal{F}} \setminus \{P\} \rangle$$

Since \mathcal{F} is a fusion system, $(\mu|_{T\mu})^{-1} \in \operatorname{Hom}_{\mathcal{F}}(T\mu, T)$ for each $\mu \in \mathcal{A}(Q)$ and $Q \in \mathcal{Q}^{\geq T}$. Therefore $C_T \leq \operatorname{Aut}_{\mathcal{F}}(T)$ and then $B_P, A_P \leq \operatorname{Aut}_{\mathcal{F}}(P)$.

Proposition 3.6. For $P \leq S$, we have $\operatorname{Aut}_{\mathcal{F}}(P) = A_P$.

Proof. By definition and construction we have $A_P \leq \operatorname{Aut}_{\mathcal{F}}(P)$. Suppose that $\alpha \in \operatorname{Aut}_{\mathcal{F}}(P)$. Since $\mathcal{F} = \mathcal{F}(\mathcal{D})$, for some $k \geq 1$ there exist $Q_1, Q_2, \ldots, Q_k \in \mathcal{Q}$ and $\widehat{\alpha}_i \in \mathcal{A}(Q_i)$ such that $P \leq Q_1$, and setting $P_0 = P$, and for $i \geq 1$, $P_i = P_{i-1}\widehat{\alpha}_i$ and $\alpha_i = \widehat{\alpha}_i|_{P_{i-1}}$ we have

$$\alpha = \alpha_1 \alpha_2 \cdots \alpha_k.$$

Since $\alpha \in \operatorname{Aut}_{\mathcal{F}}(P)$, we have $P = P_k$. Notice it may well be that $Q_1 = S$ and that P_2 is the element of S/\mathcal{D} which represents P. By examining the product $\alpha_1\alpha_2\cdots\alpha_k$, we intend to show that α may be written as a product of elements in A_P . By definition for each $0 \leq i \leq k-1$ we have $\alpha_{i+1} = \mu|_{P_i}$ for some $\mu \in \mathcal{A}(Q_{i+1})$ with $P_i \leq Q_{i+1}$. Hence $\Theta_{P_i,P_{i+1}}\alpha_{i+1}^{-1} \in C_{P_i}$ and we may write $\alpha_{i+1} = c_i \Theta_{P_i,P_{i+1}}$ for some $c_i \in C_{P_i}$. Now we have

$$\begin{aligned} \alpha &= \alpha_{1} \cdots \alpha_{k} \\ &= c_{0} \Theta_{P,P_{1}} c_{1} \Theta_{P_{1},P_{2}} \cdots c_{k-1} \Theta_{P_{k-1},P} \\ &= c_{0} (\Theta_{P,P_{1}} c_{1} \Theta_{P_{1},P}) \Theta_{P,P_{1}} \Theta_{P_{1},P_{2}} c_{2} \Theta_{P_{2},P_{3}} c_{3} \Theta_{P_{3},P_{4}} c_{4} \cdots c_{k-1} \Theta_{P_{k-1},P} \\ &= c_{0} (\Theta_{P,P_{1}} c_{1} \Theta_{P_{1},P}) (\Theta_{P,P_{1}} \Theta_{P_{1},P_{2}} c_{2} \Theta_{P_{2},P_{1}} \Theta_{P_{1},P}) \Theta_{P,P_{1}} \Theta_{P_{1},P_{2}} \Theta_{P_{2},P_{3}} c_{3} \Theta_{P_{3},P_{4}} c_{4} \cdots c_{k-1} \Theta_{P_{k-1},P} \\ &\vdots \\ &= c_{0} \prod_{i=1}^{k-1} (\Theta_{P,P_{1}} \dots \Theta_{P_{i-1},P_{i}} c_{i} \Theta_{P_{i},P_{i-1}} \dots \Theta_{P_{1},P}) \cdot \Theta_{P,P_{1}} \Theta_{P_{1},P_{2}} \dots \Theta_{P_{k-1},P} \end{aligned}$$

Now fix $1 \leq i \leq k-1$ and set $\beta_i = \Theta_{P,P_1} \dots \Theta_{P_{i-1},P_i} c_i \Theta_{P_i,P_{i-1}} \dots \Theta_{P_1,P}$. We claim that $\beta_i \in A_P$. By definition of A_P , for each $1 \leq j \leq i-1$ we have

(3.1)
$$\Theta_{P,P_i}\Theta_{P_i,P_{i+1}}\Theta_{P_{i+1},P} = h_j$$

for some $h_j \in A_P$. Hence:

$$\begin{aligned} \beta_{i} &= \Theta_{P,P_{1}}\Theta_{P_{1},P_{2}}\Theta_{P_{2},P_{3}}\Theta_{P_{3},P_{4}}\cdots\Theta_{P_{i-1},P_{i}}c_{i}\Theta_{P_{i},P_{i-1}}\cdots\Theta_{P_{4},P_{3}}\Theta_{P_{3},P_{2}}\Theta_{P_{2},P_{1}}\Theta_{P_{1},P} \\ &= h_{1}\Theta_{P,P_{2}}\Theta_{P_{2},P_{3}}\Theta_{P_{3},P_{4}}\cdots\Theta_{P_{i-1},P_{i}}c_{i}\Theta_{P_{i},P_{i-1}}\cdots\Theta_{P_{4},P_{3}}\Theta_{P_{3},P_{2}}\Theta_{P_{2},P}h_{1}^{-1} \\ &= h_{1}h_{2}\Theta_{P,P_{3}}\Theta_{P_{3},P_{4}}\cdots\Theta_{P_{i-1},P_{i}}c_{i}\Theta_{P_{i},P_{i-1}}\cdots\Theta_{P_{4},P_{3}}\Theta_{P_{3},P}h_{2}^{-1}h_{1}^{-1} \\ &\vdots \\ &= h_{1}h_{2}\cdots h_{i-1}\Theta_{P,P_{i}}c_{i}\Theta_{P_{i},P}h_{i-1}^{-1}h_{i-2}^{-1}\cdots h_{1}^{-1} \in A_{P} \end{aligned}$$

since $\Theta_{P,P_i} c_i \Theta_{P_i,P} \in B_P \leq A_P$.

Finally, setting $\beta = \prod_{i=1} \beta_i$ and letting h_j be defined as in (3.1) in the case i = k - 1 we have,

$$\begin{aligned} \alpha &= c_0 \beta \cdot \Theta_{P,P_1} \Theta_{P_1,P_2} \Theta_{P_2,P_3} \Theta_{P_3,P_4} \cdots \Theta_{P_{k-1},P} \\ &= c_0 \beta \cdot h_1 \Theta_{P,P_2} \Theta_{P_2,P_3} \Theta_{P_3,P_4} \cdots \Theta_{P_{k-1},P} \\ &= c_0 \beta \cdot h_1 h_2 \Theta_{P,P_3} \Theta_{P_3,P_4} \cdots \Theta_{P_{k-1},P} \\ &\vdots \\ &= c_0 \beta \cdot h_1 h_2 \cdots h_{k-2} \in A_P, \end{aligned}$$

as required.

Remark 3.7. We make some remarks concerning the efficient computation of A_P from Γ . For $X \in \Gamma(P)$, we fix a transversal \mathcal{T}_X to $N_{\mathcal{A}(S)}(X)$ in $\mathcal{A}(S)$ which contains $1_{\mathcal{A}(S)}$. Then $X^{\mathcal{A}(S)} = \{X\beta \mid \beta \in \mathcal{T}_X\}$. For $X, Y \in \Gamma(P), X' \in X^{\mathcal{A}(S)}$ and $Y' \in Y^{\mathcal{A}(S)}$ we first define $\Theta_{X',Y'} = \beta^{-1}\Theta_{X,Y}\delta$ where $\beta \in \mathcal{T}_X, \delta \in \mathcal{T}_Y$ with $X' = X\beta$ and $Y' = Y\delta$. With this definition, for $X, Y \in \Gamma(P)$, we have

$$\Theta_{P,X'}\Theta_{X',Y'}\Theta_{Y',P} = \Theta_{P,X}\Theta_{X,Y}\Theta_{Y,P}.$$

Hence

$$\operatorname{Aut}_{\mathcal{F}}(P) = \langle B_P, \Theta_{P,X} \Theta_{X,Y} \Theta_{Y,P} \mid X, Y \in \Gamma(P) \rangle$$

Now a typical generator of B_P has the form

$$\Theta_{P,X'}\Theta_{X',Y'}\mu^{-1}|_{Y'}\Theta_{X',P}$$

where $X', Y' \leq Q \in \mathcal{Q}$ and $\mu \in \mathcal{A}(Q)$. Notice that

$$\Theta_{P,X'} \Theta_{X',Y'} \mu^{-1}|_{Y'} \Theta_{X',P} = \Theta_{P,X} \beta \beta^{-1} \Theta_{X,Y} \delta \mu^{-1}|_{Y'} \beta^{-1} \Theta_{X,P}$$
$$= \Theta_{P,X} \Theta_{X,Y} \delta \mu^{-1}|_{Y'} \beta^{-1} \Theta_{X,P}.$$

Thus

$$B_P = \langle \Theta_{P,X} \Theta_{X,Y} \delta \mu^{-1} |_{Y'} \beta^{-1} \Theta_{X,P} \rangle$$

where

- (1) X, Y are vertices in $\Gamma(P)$;
- (2) $\beta \in \mathcal{T}_X$ and $\delta \in \mathcal{T}_Y$ are such that $\langle X\beta, Y\delta \rangle \leq Q$ for some $Q \in \mathcal{Q}$; and
- (3) $\mu \in \mathcal{A}(Q)$ is such that $X\beta\mu = Y\delta$.

Finally, to avoid running over all the elements of $\mathcal{A}(Q)$, we note that we can write $\mu = \sigma \tau$ where $\sigma \in N_{\mathcal{A}(Q)}(X\beta)$. Thus in practice we add all $\Theta_{P,X}\Theta_{X,Y}\delta\rho^{-1}|_{Y'}\beta^{-1}\Theta_{X,P}$ to B_P where ρ runs through a set of generators for $N_{\mathcal{A}(Q)}(X\beta)$ and then run through a transversal of $N_{\mathcal{A}(Q)}(X\beta)$ in

 $\mathcal{A}(Q)$. Furthermore, we note that, if $T \in P^{\mathcal{F}}$ with $T \leq Q \in \mathcal{Q}$, then, as A_P contains all elements of the form $\Theta_{P,T}\Theta_{T,R}\Theta_{R,P}$, for $\mu \in \mathcal{A}(Q)$ we have $\Theta_{P,T}\Theta_{T,T\mu}\mu^{-1}\Theta_{T,P} \in A_P$ if and only if

$$(\Theta_{P,T}\Theta_{T,T\mu}\Theta_{T\mu,P})^{-1}\Theta_{P,T}\Theta_{T,T\mu}\mu^{-1}\Theta_{T,P}(\Theta_{P,T}\Theta_{T,T\mu}\Theta_{T\mu,P}) \in A_P$$

if and only if

$$\Theta_{P,T\mu}\mu^{-1}\Theta_{T,T\mu}\Theta_{T\mu,P} \in A_P$$

if and only if

$$\Theta_{P,T\mu}\Theta_{T\mu,T}\mu\Theta_{T\mu,P} \in A_P.$$

This means that we only need to add automorphisms to B_P which correspond to $\mathcal{A}(Q)$ -orbit representatives of elements of $\Gamma(P)$ contained in Q.

Motivated by saturated fusion systems, we make the following definition:

Definition 3.8. Let $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ be a fusion datum on S with fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$. Then \mathcal{D} is an *automizer sequence* on S if for each $Q \in \mathcal{Q}$:

- (1) $\mathcal{A}(Q) = \operatorname{Aut}_{\mathcal{F}}(Q);$
- (2) Q is \mathcal{F} -centric;
- (3) Aut_S(Q) is a Sylow p-subgroup of $\mathcal{A}(Q)$;
- (4) for $Q \neq S$, $\mathcal{A}(Q) / \operatorname{Inn}(Q)$ has a strongly *p*-embedded subgroup.

Suppose that \mathcal{D} is an automizer sequence. Then $\mathcal{A}(S)$ has $\operatorname{Inn}(S)$ as a normal subgroup and $\mathcal{A}(S)/\operatorname{Inn}(S)$ is a p'-group by Definition 3.8(3). By the Schur–Zassenhaus Theorem [Gor80, Theorem 6.2.1], $\mathcal{A}(S)$ has a complement K to $\operatorname{Inn}(S)$. The group $B = S \rtimes K$ has $S \in \operatorname{Syl}_p(B)$ and satisfies $\operatorname{Aut}_B(S) = \mathcal{A}(S)$ and $B/S \cong \mathcal{A}(S)/\operatorname{Inn}(S) \cong K$. We refer to the group B as the Borel group of \mathcal{D} . Using $\Gamma(\mathcal{D})$, we can determine whether or not all points in Definition 3.8 hold. We also have the following observation which summarises our discussion so far.

Theorem 3.9. Let \mathcal{D} be a fusion datum on S with fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$. The procedures described above can be used to calculate $\operatorname{Aut}_{\mathcal{F}}(P)$ for all subgroups $P \leq S$, determine \mathcal{F} -conjugacy between subgroups and check if \mathcal{D} is an automizer sequence.

We now turn to the precise relationship between automizer sequences and saturated fusion systems:

Definition 3.10. Let \mathcal{F} be a saturated fusion system on S. An Alperin sequence \mathcal{D} associated to \mathcal{F} is a fusion datum $(\mathcal{Q}, \mathcal{A})$ such that

- (1) $\mathcal{Q} \subseteq \mathcal{E}_{\mathcal{F}} \cup \{S\}$ contains a set of \mathcal{F} -conjugacy class representatives of $\mathcal{E}_{\mathcal{F}}$;
- (2) $\mathcal{A}(Q) = \operatorname{Aut}_{\mathcal{F}}(Q)$ for each $Q \in \mathcal{Q}$.

Proposition 3.11. If \mathcal{D} is an Alperin sequence associated to a saturated fusion system \mathcal{F} then \mathcal{D} is an automizer sequence and $\mathcal{F} = \mathcal{F}(\mathcal{D})$.

Proof. Since \mathcal{F} is saturated, S is fully \mathcal{F} -automized and $p \nmid |\operatorname{Out}_{\mathcal{F}}(S)|$ so part (3) holds in Definition 3.8 in the case Q = S. The remaining parts of the definition follow easily, so \mathcal{D} is an automizer sequence. We obtain $\mathcal{F} = \mathcal{F}(\mathcal{D})$ from Theorem 2.4 and Lemma 2.5.

The converse statement also holds:

Proposition 3.12. Let \mathcal{D} be an automizer sequence on S with fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$. If \mathcal{F} is saturated, then \mathcal{D} is an Alperin sequence associated to \mathcal{F} .

We prove this in a series of lemmas. Recall that, following [AKO11, Proposition I.3.3(b)], if P < S is fully \mathcal{F} -normalized, $H_{\mathcal{F}}(P)$ is defined to be the subgroup of $\operatorname{Aut}_{\mathcal{F}}(P)$ which is generated by those \mathcal{F} -automorphisms of P which extend to \mathcal{F} -isomorphisms between strictly larger subgroups of S. By [AKO11, Proposition I.3.3 (b)], if P is fully \mathcal{F} -normalized and $H_{\mathcal{F}}(P) < \operatorname{Aut}_{\mathcal{F}}(P)$, then $H_{\mathcal{F}}(P)/\operatorname{Inn}(P)$ is strongly p-embedded in $\operatorname{Out}_{\mathcal{F}}(P)$. Consequently, $H_{\mathcal{F}}(P) < \operatorname{Aut}_{\mathcal{F}}(P)$ if and only if P is \mathcal{F} -essential.

Lemma 3.13. Suppose that \mathcal{F} is saturated and Q < S is fully \mathcal{F} -normalized. Let \mathcal{Q}_0 be the set of all subgroups of S which are not \mathcal{F} -conjugate to Q. Then $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(P) \mid P \in \mathcal{Q}_0 \rangle$ if and only if $Q \notin \mathcal{E}_{\mathcal{F}}$.

Proof. Set $\mathcal{F}_0 = \langle \operatorname{Aut}_{\mathcal{F}}(P) \mid P \in \mathcal{Q}_0 \rangle$. If $Q \notin \mathcal{E}_{\mathcal{F}}$, then \mathcal{Q}_0 contains $\mathcal{E}_{\mathcal{F}}$ so $\mathcal{F} = \mathcal{F}_0$ by Theorem 2.4. Conversely, assume that $Q \in \mathcal{E}_{\mathcal{F}}$. It suffices to prove that $H_{\mathcal{F}}(Q) = \operatorname{Aut}_{\mathcal{F}_0}(Q)$, for then $\operatorname{Aut}_{\mathcal{F}_0}(Q) = H_{\mathcal{F}}(Q) < \operatorname{Aut}_{\mathcal{F}}(Q)$ by [AKO11, Proposition I.3.3(b)] and $\mathcal{F} \neq \mathcal{F}_0$, as needed. If $\varphi \in \operatorname{Aut}_{\mathcal{F}_0}(Q)$, there exist subgroups $Q = Q_0, Q_1, \ldots, Q_n = Q$ and P_1, \ldots, P_n of S and automorphisms $\psi_i \in \operatorname{Aut}_{\mathcal{F}}(P_i)$ such that

$$|P_i| > |Q|, \ Q_{i-1}\psi_i = Q_i \text{ and } \varphi = \psi_1|_{Q_0}\psi_2|_{Q_1}\cdots\psi_n|_{Q_{n-1}}.$$

For $1 \leq i \leq n-1$, let $\chi_i = \psi_{i+1}|_{Q_i} \cdots \psi_n|_{Q_{n-1}} \in \operatorname{Hom}_{\mathcal{F}}(Q_i, Q)$. Since $\operatorname{Aut}_S(Q_i)^{\chi_i}$ is a *p*-subgroup of $\operatorname{Aut}_{\mathcal{F}}(Q)$ and *Q* is fully \mathcal{F} -automized, there exists $\eta_i \in \operatorname{Aut}_{\mathcal{F}}(Q)$ with $\operatorname{Aut}_S(Q_i)^{\chi'_i} \leq \operatorname{Aut}_S(Q)$ where $\chi'_i = \chi_i \eta_i \in \operatorname{Hom}_{\mathcal{F}}(Q_i, Q)$. Set $\chi'_0 = \chi'_n = \operatorname{Id}_Q$ and $\theta_i = (\chi'_{i-1})^{-1} \psi_i|_{Q_{i-1}}\chi'_i \in \operatorname{Aut}_{\mathcal{F}}(Q)$ for $1 \leq i \leq n$. Now,

$$\operatorname{Aut}_{S}(Q)^{\theta_{i}} \cap \operatorname{Aut}_{S}(Q) \geq \operatorname{Aut}_{S}(Q)^{\left(\chi_{i-1}^{\prime}\right)^{-1}\psi_{i}|_{Q_{i-1}}\chi_{i}^{\prime}} \cap \operatorname{Aut}_{S}(Q_{i})^{\chi_{i}^{\prime}}} \\ \geq \operatorname{Aut}_{S}(Q_{i-1})^{\psi_{i}|_{Q_{i-1}}\chi_{i}^{\prime}} \cap \operatorname{Aut}_{S}(Q_{i})^{\chi_{i}^{\prime}}} \\ \geq \operatorname{Aut}_{P_{i}}(Q_{i-1})^{\psi_{i}|_{Q_{i-1}}\chi_{i}^{\prime}} \cap \operatorname{Aut}_{S}(Q_{i})^{\chi_{i}^{\prime}}} \\ = \operatorname{Aut}_{P_{i}}(Q_{i})^{\chi_{i}^{\prime}} \cap \operatorname{Aut}_{S}(Q_{i})^{\chi_{i}^{\prime}}} \\ = \operatorname{Aut}_{P_{i}}(Q_{i})^{\chi_{i}^{\prime}} > \operatorname{Inn}(Q_{i})^{\chi_{i}^{\prime}} = \operatorname{Inn}(Q),$$

so $\theta_i \in H_{\mathcal{F}}(Q)$ by [AKO11, proof of Proposition I.3.3(b)] and then $\varphi = \theta_1 \theta_2 \cdots \theta_n \in H_{\mathcal{F}}(Q)$. Plainly $H_{\mathcal{F}}(Q) \leq \operatorname{Aut}_{\mathcal{F}_0}(Q)$, so $H_{\mathcal{F}}(Q) = \operatorname{Aut}_{\mathcal{F}_0}(Q)$ and the result follows.

Lemma 3.14. Let \mathcal{F} be a saturated fusion system on S. Let \mathcal{E} be a set of subgroups of S such that $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{E} \rangle$. Then there exists a subset $\mathcal{E}^{\circ} \subseteq \mathcal{E}$ of \mathcal{F} -conjugacy class representatives of \mathcal{F} -essential subgroups.

Proof. If Q is \mathcal{F} -essential, then the \mathcal{F} -automorphism groups of all subgroups of S which are not \mathcal{F} -conjugate to Q does not generate \mathcal{F} by Lemma 3.13. It follows that Q must be \mathcal{F} -conjugate to an element of \mathcal{E} .

Proof of Proposition 3.12. Write $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$. As \mathcal{D} is an automizer sequence, $\operatorname{Aut}_{\mathcal{F}}(Q) = \mathcal{A}(Q)$ for each $Q \in \mathcal{Q}$. Since $\mathcal{F} = \mathcal{F}(\mathcal{D})$, Lemma 3.14 implies every \mathcal{F} -essential subgroup is \mathcal{F} -conjugate to an element of \mathcal{Q} . Conversely, for any $Q \in \mathcal{Q}$, Q < S is fully \mathcal{F} -automized by Definition 3.8 (1) and (3) and fully \mathcal{F} -centralized (it is \mathcal{F} -centric by Definition 3.8 (2)). Therefore Q is fully \mathcal{F} -normalized and hence \mathcal{F} -essential by Definition 3.8 (4). Thus $\mathcal{Q} \subseteq \mathcal{E}_{\mathcal{F}} \cup \{S\}$. This completes the proof.

The problem of determining whether or not the fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$ of a given automizer sequence \mathcal{D} is saturated reduces to checking whether or not \mathcal{D} is an Alperin sequence. By Theorem 3.9, we can solve this problem by checking that the surjectivity property holds for fully \mathcal{F} -normalized \mathcal{F} -conjugacy class representatives of \mathcal{F} -centric subgroups. Furthermore, by the remark after Theorem 2.3, we only have to check that each connected component of the fusion graph $\Gamma(\mathcal{D})$ has a vertex which satisfies the surjectivity property. This produces a command for a sequence $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ with fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$: IsSaturated(F).

3.1. Implementation. We have created a type in MAGMA called FusionSystem and accompanying this we have a command CreateFusionSystem which takes as its input a sequence A of automorphism groups from the fusion datum $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$. The declaration F:=CreateFusionSystem(A) calculates and then assigns a number of attributes to the object F:

F'group:	the p -group S
F'prime:	the prime p
F'borel:	the Borel group of \mathcal{F}
F'essentials:	the sequence \mathcal{Q} (starting with S)
F'essentialautos:	the sequence of automorphism groups \mathcal{A}
F'subgroups:	the subgroups of S up to B -conjugacy
F'AutF:	an associative array indexed over F'subgroups where $\operatorname{Aut}_{\mathcal{F}}(P)$
	is stored as it is made.

Once the fusion graph has been calculated, the attribute F'fusiongraph is assigned and, if IsSaturated(F) has been executed, then we also record the outcome as F'saturated.

4. Searching for saturated fusion systems

Let S be a finite p-group. We now address the problem of determining automizer sequences $(\mathcal{Q}, \mathcal{A})$ on S which could potentially give rise to a saturated fusion system \mathcal{F} with the properties that $O^p(\mathcal{F}) = \mathcal{F}$ and $O_p(\mathcal{F}) = 1$. Similarly to the strategy in [AOV17] we first analyze the p-group on its own before we go to the expense of calculating all the potential Borel groups associated with S. The input for the procedure is a p-group S. We immediately transform S into a PCGroup, a group given by a power commutator presentation, as the calculations that we will perform are more timely with groups in this category. Thus S := PCGroup(S).

The first lemma tells us not to consider abelian groups.

Lemma 4.1. Suppose that \mathcal{F} is a saturated fusion system on a non-trivial p-group S with $O_p(\mathcal{F}) = 1$. Then S is non-abelian.

Proof. This is well-known and follows from Theorem 2.4.

We can also exclude the case when Aut(S) is a p-group when $p \ge 5$:

Lemma 4.2. Let $p \ge 5$. If \mathcal{F} is a saturated fusion system on a non-trivial p-group S such that $\operatorname{Aut}_{\mathcal{F}}(S)$ is a p-group, then $\mathfrak{foc}(\mathcal{F}) < S$.

Proof. See [DGMP10, Corollary 6.2].

The next lemma removes groups where the centre has small index.

Lemma 4.3. Suppose that S is non-trivial, \mathcal{F} is a saturated fusion system on S with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. If $|S : Z(S)| \leq p^2$, then $S \cong p_+^{1+2}$. In particular, all such fusion systems are known.

Proof. Since $|S : Z(S)| \leq p^2$ and S is non-abelian by Lemma 4.1, S/Z(S) is not cyclic and so S has at least three abelian maximal subgroups and $|S : Z(S)| = p^2$. If p is odd, then $S \cong p_+^{1+2}$ by [Oli14, Theorem 2.1] (in fact the hypothesis of this theorem requires \mathcal{F} is reduced but the proof only uses $O_p(\mathcal{F}) = 1$). So suppose that p = 2. In this case [Oli14, Lemma 1.9] implies S' has order 2. Noting that [AOV13, Proposition 2.5] only uses $O^2(\mathcal{F}) = \mathcal{F}$ and $O_2(\mathcal{F}) = 1$, we apply this result and using |S : Z(S)| = 4 completes the proof that $S \cong p_+^{1+2}$. Using [AKO11, Example I.2.7] and [RV04, Theorem 1.1], we obtain a description of all the fusion systems.

Since we are interested in finding potential \mathcal{F} -essential subgroups E and these subgroups have the property that $\operatorname{Out}_{\mathcal{F}}(E)$ has a strongly *p*-embedded subgroup we collect some facts about such groups. Recall that a finite group is *almost simple* if and only if it has a unique minimal normal subgroup and this subgroup is simple and non-abelian.

Lemma 4.4. Suppose that p is a prime and H is a group with a strongly p-embedded subgroup M. If M contains an elementary abelian subgroup A of order p^2 , then $O_{p'}(H) \leq M$, $M/O_{p'}(H)$ is strongly p-embedded in $H/O_{p'}(H)$ and $H/O_{p'}(H)$ is an almost simple group.

Proof. Set $R = O_{p'}(H)$ and let $T \in \operatorname{Syl}_p(M)$. Then, by [GLS96, Proposition 11.23] (coprime action), $R = \langle C_R(a) \mid a \in A^{\#} \rangle$. Since $C_H(a) \leq M$, for all $a \in A^{\#}$, $R \leq M$. Then M/R is strongly p-embedded in H/R. Henceforth, we assume that R = 1. Since $O_p(H) = 1 = R$, the minimal normal subgroups of H are non-abelian. Let N be such a minimal normal subgroup. Then N has order divisible by p and $N \not\leq M$ as otherwise $M \geq N_H(N \cap T)N = H$ by the Frattini Argument. Let N_1 be a simple factor in N and let $C = C_H(N_1)$. If $T \cap C \neq 1$, then $N_1 \leq C_H(T \cap C) \leq M$ and $C \leq C_H(N_1 \cap T) \leq M$. Thus $N = N_1C_N(N_1) \leq N_1C \leq M$, a contradiction. Therefore $T \cap C = 1$. Thus $N = N_1$, and C is normal in H. Now $T \cap C = 1$ implies $C \leq O_{p'}(H) = 1$ and so H embeds into Aut(N). This proves the claim.

The next proposition is proved by analysing generation properties of the finite simple groups. This means that it is known only due to the classification theorem of the finite simple groups.

Proposition 4.5. Suppose that p is a prime, X is a group, $K = F^*(X)$ and $T \in Syl_p(X)$. Assume that $O_{p'}(X) = 1$ and that M is a strongly p-embedded subgroup of X containing T. Then $O_p(X) = 1$, K is a non-abelian simple group, $M \cap K$ is strongly p-embedded in K, and p and K are as follows:

- (1) p is arbitrary, $a \ge 1$ and $K \cong PSL_2(p^{a+1})$, $PSU_3(p^a)$ $(p^a \ne 2)$, ${}^2B_2(2^{2a+1})$ (p = 2) or ${}^2G_2(3^{2a+1})$ (p = 3) and X/K is a p'-group.
- (2) p > 3, $K \cong Alt(2p)$, $|X/K| \le 2$ and T is elementary abelian of order p^2 .
- (3) p = 3, $K \cong PSL_2(8)$, $X \cong Aut(PSL_2(8)) \cong {}^2G_2(3) \cong PSL_2(8)$:3, $T \cong 3_{-}^{1+2}$ and $T \cap K$ is cyclic of order 9.
- (4) p = 3, $K \cong PSL_3(4)$, X/K is a 2-group and T is elementary abelian of order 3^2 .
- (5) p = 3, $X = K \cong M_{11}$ and T is elementary abelian of order 3^2 .
- (6) $p = 5, K \cong {}^{2}B_{2}(32), X \cong Aut({}^{2}B_{2}(32)) \cong {}^{2}B_{2}(32):5, T \cong 5_{-}^{1+2} and T \cap K is cyclic of order 25.$
- (7) p = 5, $K \cong {}^{2}F_{4}(2)'$, $|X/K| \leq 2$ and T is elementary abelian of order 5^{2} .
- (8) $p = 5, K \cong \text{McL}, |X/K| \le 2 \text{ and } T \cong 5^{1+2}_+.$
- (9) p = 5, $K \cong Fi_{22}$, $|X/K| \le 2$ and T is elementary abelian of order 5^2 .
- (10) p = 11, $X = K \cong J_4$ and $T \cong 11^{1+2}_+$.
- (11) p is odd and $T = T \cap K$ is cyclic.

Proof. Using [GLS99, Chapter 4, Lemma 10.3] yields that K is a non-abelian simple group, $M \cap K$ is strongly *p*-embedded in K and either $T \leq K$ or (3) or (6) holds. If T is cyclic, then this case is listed as (11). Using [GLS99, Chapter 4, Proposition 10.2] yields the possibilities for K when T is not cyclic. The description of |X/K| follows from the structure of the automorphism group of K as described in [GLS98, Theorem 2.5.12, Theorem 5.2.1, Table 5.3]. Finally, the Sylow *p*-subgroup structure listed of the groups in (2)-(10) is either easy to write down or follows from [GLS98, Table 5.3] for the sporadic groups.

To ease application of Proposition 4.5 we record the following elementary consequence:

Corollary 4.6. Suppose that H is a group with a strongly p-embedded subgroup and let $T \in$ Syl_p(H). Then one of the following holds:

- (1) T is cyclic or quaternion;
- (2) T is elementary abelian of order at least p^2 ;
- (3) $p^a \neq 2$ and T is isomorphic to a Sylow p-subgroup of $PSU_3(p^a)$ and has order p^{3a} ;
- (4) p = 2, and T is isomorphic to a Sylow 2-subgroup of ${}^{2}B_{2}(2^{a})$ and has order 2^{2a} for some odd integer $a \geq 3$;
- (5) p = 3 and T is isomorphic to a Sylow 3-subgroup of ${}^{2}G_{2}(3^{a})$ and has order 3^{3a} for some odd integer $a \ge 1$; or
- (6) p = 5 and $T \cong 5^{1+2}_{-}$ is extraspecial.

Furthermore, if H is soluble, then T is quaternion or cyclic.

Proof. We may assume that (1) is false. In this case, [Gor80, Theorem 5.4.10 (ii)] states that T contains an elementary abelian subgroup of order p^2 . By Lemma 4.4, $H/O_{p'}(H)$ is an almost simple group with a strongly p-embedded subgroup. The result now follows from Proposition 4.5 applied to $H/O_{p'}(H)$.

When p = 2, the following lemma is [OV09, Lemma 1.7(a)].

Lemma 4.7. Suppose that H has a strongly p-embedded subgroup, $T \in Syl_p(H)$ and V is a faithful GF(p)H-module. Then $|V| \ge |T|^2$.

Proof. By [OV09, Lemma 1.7(a)] we may assume that p is odd. We suppose that the conclusion of the lemma is false, that is $|V| < |T|^2$. If |T| = p, then $|V| \le p$ and we have a contradiction as p divides |H|. Hence |T| > p.

Suppose that T is cyclic of order $p^a > p$. Then the Jordan form of a generator of T has a block of at least size $p^{a-1} + 1$ and so

$$(a-1)p+1 \le p^{a-1}+1 < 2a.$$

But then p = 2, a contradiction. Since p is odd, T is not quaternion. Hence T is neither cyclic nor quaternion so [Gor80, Theorem 5.4.10 (ii)] and Lemma 4.4 imply that $\overline{H} = H/O_{p'}(H)$ is an almost simple group with a strongly p-embedded subgroup and the isomorphism type of this group is given by Proposition 4.5. Suppose that $F^*(\overline{H}) \cong \operatorname{Alt}(2p)$. Then $|V| \leq p^3$ and $|F^*(\overline{H})|$ divides $|\operatorname{GL}_3(p)|$. However, $|\operatorname{Alt}(6)|$ does not divide $|\operatorname{GL}_3(3)|$ (as the latter group has order coprime to 5) and for $p \geq 5$, $|\operatorname{Alt}(2p)| > |\operatorname{GL}_3(p)|$: this is immediate to check if p = 5; for $p \geq 7$, we have $p^9 > |\operatorname{GL}_3(p)|$ and $(2n)!/2 > n^9$ for $n \geq 6$ by induction. If p = 3 and $F^*(\overline{H}) \cong \operatorname{PSL}_3(4)$, or M_{11} , then $|V| < |T|^2 = 3^4$ and we have a contradiction as 5 does not divide $|\operatorname{GL}_3(3)|$. If p = 5, and $F^*(\overline{H}) \cong {}^2\mathrm{F}_4(2)'$, Fi₂₂ or McL, then $|V| < |T|^2 = 5^4$ in the first two cases and $|V| < 5^6$ in the last case. In all cases, a Sylow 3-subgroup is too big to be contained in $\operatorname{GL}(V)$. If p = 11 and $\overline{H} \cong \mathrm{J}_4$ then $|V| \leq 11^5$, however a Sylow 2-subgroup of \overline{H} is far too big for H to embed into $\operatorname{GL}_5(11)$.

In the cases when p = 3 and $F^*(\overline{H}) \cong PSL_2(8)$ or p = 5 and $F^*(\overline{H}) \cong {}^2B_2(32)$ we have $|T| \le p^3$ and so require H to embed into $GL_5(p)$. However 7 does not divide $|GL_5(3)|$ and 41 does not divide $|GL_5(5)|$.

Now Proposition 4.5 implies that $F^*(\overline{H})$ is a rank 1 Lie type group in characteristic p.

Suppose that $F^*(\overline{H}) \cong PSL_2(p^a)$. Then $|\overline{H}|$ is divisible by $p^a + 1$. Since p is odd, Zsigmondy's Theorem [Zsi92] implies that either there exists a prime r which divides $p^{2a} - 1$ but does not divide $p^b - 1$ for all $1 \leq b < 2a$ or p^a is a Mersenne prime. Since T is not cyclic, the first possibility holds. But r does not divide $|GL_{2a-1}(p)|$, and so we conclude $|V| \geq p^{2a}$ in this case.

Suppose that $F^*(\overline{H}) \cong PSU_3(p^a)$ or p = 3 and $F^*(\overline{H}) \cong {}^2G_2(p^a)$. Then \overline{H} has order divisible by $p^{3a} + 1$. Since p is odd, Zsigmondy's Theorem implies there exists a prime r which divides $p^{6a} - 1$ and which does not divide $p^b - 1$ for all $1 \leq b < 6a$. In particular r does not divide $p^{3a} - 1$, so r divides $p^{3a} + 1$ and hence also $|\overline{H}|$. Since r does not divide $|\operatorname{GL}_{6a-1}(p)|$, we have $|V| \geq p^{6a}$. \Box

Using the above observations about groups with a strongly *p*-embedded subgroup, we have the following proposition which describes the initial tests that we make. The first of these isolates subgroups of S which are potentially \mathcal{F} -essential in some saturated fusion system on S.

Proposition 4.8. Suppose that \mathcal{F} is a saturated fusion system on S and that $E \in \mathcal{E}_{\mathcal{F}}$. Then

- (1) E is S-centric;
- (2) $\operatorname{Out}_{S}(E) \cap O_{p}(\operatorname{Out}(E)) = 1;$
- (3) $\operatorname{Out}_{S}(E)$ is isomorphic to a Sylow p-subgroup of a group with a strongly p-embedded subgroup;
- (4) $|E/\Phi(E)| \ge |\operatorname{Out}_{S}(E)|^{2};$
- (5) If $\operatorname{Out}_{S}(E)$ has an elementary abelian subgroup of order p^{2} , $\operatorname{Aut}_{\mathcal{F}}(E)$ is not soluble;
- (6) $\operatorname{Out}_{S}(E)$ is abelian of order at most p^{2} whenever $|S| \leq p^{8}$.

Proof. That E is S-centric is part of the definition of being \mathcal{F} -essential. To see that (2) holds we just observe

$$\operatorname{Out}_{S}(E) \cap O_{p}(\operatorname{Out}(E)) \leq \operatorname{Out}_{\mathcal{F}}(E) \cap O_{p}(\operatorname{Out}(E)) \leq O_{p}(\operatorname{Out}_{\mathcal{F}}(E)) = 1.$$

Part (3) follows as $\operatorname{Out}_{\mathcal{F}}(E)$ has a strongly *p*-embedded subgroup. For part (4), we set $V = E/\Phi(E)$ and note that this is a faithful $\operatorname{GF}(p) \operatorname{Out}_{\mathcal{F}}(E)$ -module. Thus (4) comes from Lemma 4.7. Part (5) follows from Lemma 4.4. Finally (6) follows from (4) since, if $|\operatorname{Out}_S(E)| \ge p^3$, then $|E| \ge p^6$ and then $|S| \ge |N_S(E)| \ge p^9$.

A subgroup $E \leq S$ which satisfies conditions (1)-(6) in Proposition 4.8 is called *potentially* essential. Denote by \mathcal{P}_S the set of all potentially essential subgroups. Note that if $\mathcal{P}_S = \emptyset$, then any saturated fusion system on S satisfies $O_p(\mathcal{F}) = S$. Also note these conditions depend only upon S so that the set \mathcal{P}_S can be determined relatively quickly. Nonetheless, we need to calculate the automorphism groups of every S-centric subgroup. To make this execute more quickly, we note that, if $E \in \mathcal{P}_S$ and $\alpha \in \operatorname{Aut}(S)$, then $P\alpha \in \mathcal{P}_S$. Thus we calculate these properties just for representatives of $\operatorname{Aut}(S)$ -orbits of subgroups.

Since we are interested in saturated fusion systems \mathcal{F} with $O_p(\mathcal{F}) = 1$, we will repeatedly use the following lemma to test whether $O_p(\mathcal{F}) \neq 1$.

Lemma 4.9. Suppose that \mathcal{F} is a saturated fusion system on S and \mathcal{S} is a subset of $\mathcal{E}_{\mathcal{F}}$ which contains a set of \mathcal{F} -conjugacy class representatives of members of $\mathcal{E}_{\mathcal{F}}$. Assume that $K \leq \bigcap_{E \in \mathcal{S}} E$ is invariant under $\operatorname{Aut}_{\mathcal{F}}(E)$ for each $E \in \mathcal{S}$ and under $\operatorname{Aut}_{\mathcal{F}}(S)$. Then $K \leq O_p(\mathcal{F})$. In particular, this conclusion holds if K is characteristic in every $E \in \mathcal{S}$ and in S.

Proof. By Lemma 2.5, $\mathcal{F} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) | E \in \mathcal{S} \rangle$. Suppose that A and B are subgroups of S and $\phi \in \operatorname{Hom}_{\mathcal{F}}(A, B)$. Then $\phi = \widetilde{\phi_0}\widetilde{\phi_1}\ldots\widetilde{\phi_k}$ where, for $0 \leq i \leq k$, $\widetilde{\phi_i}$ is the restriction of a certain element $\phi_i \in \operatorname{Aut}_{\mathcal{F}}(E_i)$ for $E_i \in \mathcal{S} \cup \{S\}$. Then, as K is invariant under each ϕ_i , we have $\phi^* = \widetilde{\phi_0}^*\widetilde{\phi_1}^*\ldots\widetilde{\phi_k}^* \in \operatorname{Hom}_{\mathcal{F}}(AK, BK)$ and $K\phi^* = K$, where $\widetilde{\phi_i}^*$ is the restriction of ϕ_i to the appropriate overgroup of K. This proves the claim. \Box

We first apply Lemma 4.9 with $S = \mathcal{P}_S$. In this way we discard groups S where $O_p(\mathcal{F})$ is surely non-trivial.

We now perform our first expensive calculation. For an Aut(S)-representative $E \in \mathcal{P}_S$, we first determine the subgroups, up to $N_{\text{Aut}(E)}(\text{Aut}_S(E))$ -conjugacy, of Aut(E) which contain Aut_S(E) as a Sylow p-subgroup, and for each such subgroup K we ascertain whether or not K/Inn(E) has a strongly p-embedded subgroup. If no such subgroups exist we remove E from \mathcal{P}_S ; otherwise we store a set \mathfrak{A}_E which contains $N_{\text{Aut}(E)}(\text{Aut}_S(E))$ -conjugacy classes of subgroups we have found with the property just discussed. The elements of \mathcal{P}_S are now called proto-essential. Thus, in addition to satisfying the conditions in Proposition 4.8, a proto-essential subgroup possesses a group of outer automorphisms K with a strongly p-embedded subgroup and $\operatorname{Out}_S(E) \in \operatorname{Syl}_p(K)$.

We now need to calculate all the potential Borel groups. Thus we identify all $\operatorname{Out}(S)$ -conjugacy classes of p'-subgroups $B_0 \leq \operatorname{Out}(S)$. For each class-representative, we select a complement to $\operatorname{Inn}(S)$ and form a group B with the properties that $S \in \operatorname{Syl}_p(B)$ and $\operatorname{Out}_B(S) = B_0$ (see the remarks following Definition 3.8.) By Lemma 3.3 this is fine as we are only interested in listing fusion systems up to isomorphism. The implementation of this assumes that $\operatorname{Aut}_{\mathcal{F}}(S)$ is soluble. If this is not the case, then the execution terminates reporting that the Borel group is not soluble. For the groups considered in this article, this never happens. However, it would occur if we were to attempt to enumerate the fusion systems on an extraspecial group of order 11³ and exponent 11.

Our algorithm runs through each Borel group in turn. Note that $\operatorname{Aut}_B(E)$ must be a subgroup of $\operatorname{Aut}_{\mathcal{F}}(E)$, and so we check that for each $E \in \mathcal{P}_S$ and $K \in \mathfrak{A}_E$ there is $L \in K^{N_{\operatorname{Aut}(E)}(\operatorname{Aut}_S(E))}$ which contains $\operatorname{Aut}_B(E)$. If no such L exists then we remove K from \mathfrak{A}_E , and if \mathfrak{A}_E eventually becomes empty then we remove E from \mathcal{P}_S . We refer to this as the *extension test*.

We then expand \mathcal{P}_S to contain all *B*-conjugacy class representatives of proto-essential subgroups (and not just Aut(*S*)-conjugacy class representatives.) We call this new set \mathcal{P}_B . We determine pairs (E, A) in which $E \in \mathcal{P}_B$ and $A \leq \operatorname{Aut}(E)$ is a candidate for $\operatorname{Aut}_{\mathcal{F}}(E)$ in a saturated fusion system \mathcal{F} on *S* with Borel group *B* in which *E* is \mathcal{F} -essential. To achieve this, for each $E \in \mathcal{P}_B$, and $K \in \mathfrak{A}_E$ (transferred from the automorphism group of the *B*-conjugacy class representative in \mathcal{P}_S) we determine all $\operatorname{Aut}(E)$ -conjugates of *K* containing $\operatorname{Aut}_B(E)$ and call this set \mathfrak{A}_E^* . If *E* is a "large" proto-essential subgroup, we also require that $\operatorname{Aut}_B(E) = N_K(\operatorname{Aut}_S(E))$. The next proposition gives an account of the types of checks that we make. We think of these as basic compatibility checks.

Proposition 4.10. Suppose that $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ is an automizer sequence on S and assume that $\mathcal{F} = \mathcal{F}(\mathcal{D})$ is saturated. Let n be the largest order of an element of $\mathcal{Q} \setminus \{S\}$. The following hold:

(1) If $Q \in \mathcal{Q} \setminus \{S\}$ is such that $|N_S(Q)| > n$; or $|N_S(Q)| = n$ and $N_S(Q)$ is not $\mathcal{A}(S)$ -conjugate to an element of \mathcal{Q} then

$$N_{\mathcal{A}(Q)}(\operatorname{Aut}_{S}(Q)) = \{\varphi|_{Q} \mid \varphi \in N_{\mathcal{A}(S)}(Q)\}.$$

- (2) If $P, Q \in \mathcal{Q}$ are such that P < Q then $|N_S(P)| \ge |N_S(P\alpha)|$ for each $\alpha \in \mathcal{A}(Q)$.
- (3) If $\mathcal{R} \subseteq \mathcal{Q}$ is such that $S \in \mathcal{R}$ and there exists $T \leq S$ normalized by $\mathcal{A}(R)$ for each $R \in \mathcal{R}$ then $\operatorname{Aut}_S(T)$ is a Sylow p-subgroup of $\langle \varphi |_T \mid \varphi \in \mathcal{A}(R), R \in \mathcal{R} \rangle \leq \operatorname{Aut}(T)$.

Proof. Let $Q \in \mathcal{Q} \setminus \{S\}$ be such that $|N_S(Q)| > n$; or $|N_S(Q)| = n$ and $N_S(Q)$ is not $\mathcal{A}(S)$ conjugate to an element of \mathcal{Q} . Since \mathcal{F} is saturated, Q is receptive. Therefore each element of $N_{\mathcal{A}(Q)}(\operatorname{Aut}_S(Q))$ extends to a morphism in $\operatorname{Aut}_{\mathcal{F}}(N_S(Q))$.

The hypothesis on Q together with Theorem 2.4 imply that every \mathcal{F} -automorphism of $N_S(Q)$ is the restriction of an \mathcal{F} -automorphism of S and so

$$\operatorname{Aut}_{\mathcal{F}}(N_S(Q)) = \operatorname{Aut}_{\mathcal{A}(S)}(N_S(Q))$$

Hence, as \mathcal{D} is an automizer sequence,

$$N_{\mathcal{A}(Q)}(\operatorname{Aut}_{S}(Q)) \leq \{\varphi|_{Q} \mid \varphi \in N_{\mathcal{A}(S)}(Q)\} \leq N_{\operatorname{Aut}_{\mathcal{F}}(Q)}(\operatorname{Aut}_{S}(Q)) = N_{\mathcal{A}(Q)}(\operatorname{Aut}_{S}(Q)).$$

This proves (1).

Part (2) is immediate from the fact that P is fully \mathcal{F} -normalized. If \mathcal{R} and T are as in (3) then T is fully \mathcal{F} -normalized and $\operatorname{Aut}_S(T) \leq \langle \varphi |_T \mid \varphi \in \mathcal{A}(R), R \in \mathcal{R} \rangle$ so the conclusion follows immediately from the fact that T is fully \mathcal{F} -automized.

We run through all $\mathcal{Q} \subseteq \mathcal{P}_B$, and for each $Q \in \mathcal{Q}$, we assign $\mathcal{A}(Q) = K \in \mathfrak{A}_Q^*$. This defines a fusion datum $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ and a fusion system $\mathcal{F} = \mathcal{F}(\mathcal{D})$, and further checks are made to ensure that \mathcal{D} is consistent with being an automizer sequence. The previous calculations are performed before calculating the fusion graph which is time-consuming. Finally, we check IsSaturated(F). To reduce the amount of work, we remove \mathcal{D}^{α} , for $1 \neq \alpha \in \operatorname{Aut}(S)$ from the systems which we need to test for saturation.

One further test, with variants, is used to speed up the calculations in some stubborn cases. Recall that for r a prime, a finite group G is r-closed if $|\operatorname{Syl}_r(G)| = 1$.

Lemma 4.11. Suppose that \mathcal{F} is a saturated fusion system on S, $E_1, E_2 \in \mathcal{E}_{\mathcal{F}}$ with $E_1 = N_S(E_2)$ and $|E_1 : E_2| = p$. Set $X = \bigcap_{\alpha \in \operatorname{Aut}_{\mathcal{F}}(E_1)} E_2 \alpha$ and assume that $|E_1 : X| \leq p^2$. Then $|E_1 : X| = p^2$, $\operatorname{Aut}_{\mathcal{F}}(E_1)/C_{\operatorname{Aut}_{\mathcal{F}}(E_1)}(E_1/X)$ is p-closed and $C_{\operatorname{Aut}_{\mathcal{F}}(E_1)}(E_1/X)/\operatorname{Inn}(E_1)$ is a p'-group which is not centralized by $\operatorname{Out}_S(E_1)$. Furthermore, $|S| \geq p^{p+3}$.

Proof. Set $C = C_{\operatorname{Aut}_{\mathcal{F}}(E_1)}(E_1/X)$ and assume that $|E_1:X| \leq p^2$. As $|E_1/X| \leq p^2$, $\operatorname{Inn}(E_1) \leq C$. If $|E_1:X| = p$, then $X = E_2$ and so E_2 is normalized by $N_S(E_1)$. Since $E_1 = N_S(E_2)$, we deduce that $E_1 = S$, a contradiction. Hence $|E_1:X| = p^2$, E_1/X is elementary abelian and $\operatorname{Aut}_{\mathcal{F}}(E_1)/C$ is isomorphic to a subgroup of $\operatorname{GL}_2(p)$. If $\operatorname{Aut}_{\mathcal{F}}(E_1)/C$ has at least two Sylow *p*-subgroups, then it contains a subgroup isomorphic to $\operatorname{SL}_2(p)$ and $\operatorname{Aut}_{\mathcal{F}}(E_1)$ acts transitively on the maximal subgroups of E_1 containing X. In particular, there is an \mathcal{F} -conjugate of E_2 which is normalized by $N_S(E_1)$ and this contradicts E_2 being fully \mathcal{F} -normalized. Hence $\operatorname{Aut}_{\mathcal{F}}(E_1)/C$ is *p*-closed. Set $\overline{C} = C/\operatorname{Inn}(E_1)$ and let $R \leq N_S(E_1)$ be such that $R \geq E_1$ and $\operatorname{Aut}_R(E_1)/\operatorname{Inn}(E_1) \in \operatorname{Syl}_p(\overline{C})$. Then $\operatorname{Aut}_R(E_1)$ centralizes E_1/X and so leaves E_2 invariant. Hence $R \leq N_S(E_2) = E_1$ and $\operatorname{Aut}_R(E_1) = \operatorname{Inn}(E_1)$ as is required to show that \overline{C} is a p'-group.

Since $\operatorname{Out}_{\mathcal{F}}(E_1)$ has a strongly *p*-embedded subgroup and $\operatorname{Aut}_{\mathcal{F}}(E_1)/C$ is *p*-closed, we have $O_p(\operatorname{Out}_{\mathcal{F}}(E_1)) = 1$ and $\overline{C} \operatorname{Out}_S(E_1) \trianglelefteq \operatorname{Out}_S(E_1)$ so $O_p(\overline{C} \operatorname{Out}_S(E_1)) = 1$. In particular, \overline{C} is not centralized by $\operatorname{Out}_S(E_1)$. Hence $[\overline{C}, \operatorname{Out}_S(E_1)]$ is a non-trivial *p'*-group. Since E_2 is \mathcal{F} -centric, $|\Phi(E_1)| \ge |[E_1, E_1]| \ge |[E_2, E_1]| \ge p$. Now, as $O_p(\operatorname{Out}_{\mathcal{F}}(E_1)) = 1$, [Gor80, Theorem 5.1.4] implies that $\operatorname{Out}_{\mathcal{F}}(E_1)$ acts faithfully on $E_1/\Phi(E_1)$. By [Gor80, Theorem 5.3.2] \overline{C} acts faithfully on $X/\Phi(E_1)$. Hence the kernel of the representation $\overline{C} \operatorname{Out}_S(E_1) \to \operatorname{GL}(X/\Phi(E_1))$ is a *p*-group and thus trivial as $O_p(\overline{C} \operatorname{Out}_S(E_1)) = 1$. Therefore $\overline{C} \operatorname{Out}_S(E_1)$ acts faithfully on $X/\Phi(E_1)$.

We know \overline{C} Out_S(E_1) is *p*-soluble and so the Hall-Higman Theorem [Gor80, Theorem 11.1.1 (ii)] shows that $|X/\Phi(E_1)| \ge p^{p-1}$. Observe that $|S:X| = |S:E_1||E_1:X| \ge p^3$ so that

$$|S| = |S:X||X:\Phi(E_1)||\Phi(E_1)| \ge p^{3+(p-1)+1} = p^{p+3}$$

This completes the proof of the declared statement.

In the implementation of AllFusionSystems we output only saturated fusion systems in which $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. These properties permeate the search and we make frequent checks that our fusion data induce fusion systems with these properties. In particular we check $S = \langle g^{-1}(g\alpha) | g \in Q \in \mathcal{Q}, \alpha \in \mathcal{A}(Q) \rangle$ as is required by Lemma 2.6. We also check that for each $1 \neq T \leq \bigcap_{Q \in \mathcal{Q}} Q$, there exists $Q \in \mathcal{Q}$ and $\varphi \in \mathcal{A}(Q)$ such that $T\varphi \neq T$, as otherwise $O_p(\mathcal{F}) \neq 1$ by Theorem 2.4.

An example which illustrates the execution of the above algorithm is provided in Appendix C.

5. Saturated fusion systems on p-groups of small order

We now list the results of our calculations. We say that a p-group S has type G if S is isomorphic to a Sylow p-subgroup of G. The table headings below provide the following information about S:

• group #: the MAGMA SmallGroup identification number of S;

- sec. rank: the sectional rank of S;
- *ab. ind.* p: whether or not S has an abelian maximal subgroup;
- # s.f.s: the number of saturated fusion systems on S with $O_p(\mathcal{F}) = 1$ and $\mathcal{F} = O^p(\mathcal{F})$;
- *reference*: subsection containing precise information about these fusion systems;
- type: the type of S;
- *citation(s)*: article(s) in which saturated fusion systems on this group have been previously considered.

Recall that the sectional rank of a p-group S is the maximal number of generators needed for a subgroup of S. When S is maximal class and either a 3-group or metabelian of order at most p^6 we will often indicate its description $B(p, r; \alpha, \beta, \gamma, \delta)$ as a Blackburn group (see Appendix A.)

5.1. Groups of order p^4 . In [Mon18, Theorem 7.1] Moragues Moncho gives a list of all simple saturated fusion systems on *p*-groups of order p^4 . From [Mon18, Tables 7.1 and 7.2] we see that for each $p \ge 7$ there are exactly three such fusion systems, all on a Sylow *p*-subgroup of PSp₄(*p*): one is the *p*-fusion system of PSp₄(*p*); the others are exotic. For p = 7, these are the fusion systems listed as $\mathcal{F}(7^4, 7, 1)$, $\mathcal{F}(7^4, 7, 3)$ and $\mathcal{F}(7^4, 7, 4)$ in Table 5. When $p \le 7$ we extend his result modestly by determining the cases which are not simple but have $O_7(\mathcal{F}) = 1$ and $O^7(\mathcal{F}) = \mathcal{F}$.

Theorem 5.1. Suppose that \mathcal{F} is a saturated fusion system on a p-group of order p^4 such that $O_p(\mathcal{F}) = 1$ and $\mathcal{F} = O^p(\mathcal{F})$ with $p \in \{3, 5, 7\}$. Then S has an abelian subgroup of index p and \mathcal{F} is listed in the following table:

p	group $\#$	sec. rank	<i># s.f.s</i>	reference	type	citation(s)
3	7	3	6	A.3.1	$PSp_4(3), 3 \wr 3, B(3,4;0,0,1,0)$	[CP10],[Oli14], [COS17]
3	8	2	2	A.3.2	B(3,4;0,1,0,0), B(3,4;0,0,2,0)	[DRV07], [Oli14], [COS17]
3	9	2	7	A.3.3	$PSL_3(19), B(3,4;0,0,0,0)$	[DRV07], [Oli14], [COS17]
5	7	3	30	A.3.4	$PSp_4(5), B(5,4;0,1,0,0)$	[CP10],[Oli14], [COS17]
7	7	3	8	A.3.5	$\mathrm{PSp}_4(7), B(7,4;0,1,0,0)$	[CP10],[Oli14], [COS17]

5.2. Groups of order p^5 . For $p \in \{3, 5, 7\}$ we have the following result concerning saturated fusion systems on a group of order p^5 :

Theorem 5.2. Suppose that \mathcal{F} is a saturated fusion system on a p-group of order p^5 such that $O_p(\mathcal{F}) = 1$ and $\mathcal{F} = O^p(\mathcal{F})$ with $p \in \{3, 5, 7\}$. Then \mathcal{F} is listed in the following table:

p	group #	sec. rank	<i># s.f.s</i>	reference	type	citation(s)
3	26	2	7	A.4.1	PGL ₃ (19), $B(3,5;0,0,0,0)$	[CP10],[Oli14], [COS17]
3	51	4	9	A.4.2	Alt(12), $(3 \wr 3) \times 3$	[COS17]
5	30	4	58	A.4.3	$PGL_5(11), B(5,5;0,0,0,0)$	[CP10], [Oli14], [COS17]
7	32	4	10	A.4.4	B(7,5;0,0,0,0)	[CP10],[Oli14], [COS17]
7	37	3	1	A.4.5	B(7,5;0,1,0,0)	[Gra19]

Together with results of Grazian [Gra19] for $p \ge 5$, Theorem 5.2 completes the classification of saturated fusion systems \mathcal{F} on p-groups of order p^5 in which $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. For p = 2, the result for reduced fusion systems is [AOV13, Theorem 5.3].

Corollary 5.3. Suppose that $p \ge 3$, S is a p-group and \mathcal{F} is a saturated fusion system on S with $\mathcal{F} = O^p(\mathcal{F})$ and $O_p(\mathcal{F}) = 1$. If $|S| = p^5$, then either S has an abelian subgroup of index p or S is SmallGroup(7⁵, 37) and \mathcal{F} is the Grazian fusion system. In particular, all saturated fusion systems on p-groups of order p^5 with $\mathcal{F} = O^p(\mathcal{F})$ and $O_p(\mathcal{F}) = 1$ are known.

Proof. Assume that S has no abelian subgroups of index p. If S has sectional rank 2, then it has rank 2 and by [DRV07] we have p = 3. In any case, if p = 3, the result follows from Theorem 5.2. Hence we may suppose that $p \ge 5$. Assume that S has sectional rank 3. By [Gra19, Theorem C], since $|S| = p^5$, p = 7 and \mathcal{F} is the unique saturated fusion system on SmallGroup(7⁵, 37) which has $O_7(\mathcal{F}) = 1$ and $O^7(\mathcal{F}) = \mathcal{F}$. So suppose that S has sectional rank at least 4. Since S is not abelian, S has sectional rank 4. If any maximal subgroup of S has rank at most 3 and so, as S has sectional rank 4, we have $|S/\Phi(S)| = p^4$ and $|\Phi(S)| = p$. Suppose that $E \le S$ is an \mathcal{F} -essential subgroup of S. Then $\Phi(S) \le Z(S) \le E$. In particular, E is normal in S and $\Phi(E) \le \Phi(S)$. Since $[E, S] \not\le \Phi(E)$ we infer that E is elementary abelian. Hence $|E| \le p^3$ as S has no abelian subgroups of index p. Since $C_S(E) = E$, we have $\operatorname{Aut}_S(E)$ has order at least p^2 . However then $|E| < |\operatorname{Out}_S(E)|^2$ and this contradicts Lemma 4.7.

Remark 5.4. If we relax the assumption that $O^p(\mathcal{F}) = \mathcal{F}$ in Corollary 5.3, then we need to add the new saturated fusion system on S = B(3,5;0,1,0,0) discovered in [PS19]. This has a subsystem isomorphic with the 3-fusion system of PSL₃(19) with index 3.

5.3. Groups of order p^6 . Next, we consider saturated fusion systems on groups of order p^6 with $p \in \{3, 5\}$.

Theorem 5.5. Suppose that \mathcal{F} is a saturated fusion system on a p-group of order p^6 with $O_p(\mathcal{F}) = 1$ and $\mathcal{F} = O^p(\mathcal{F})$ with $p \in \{3, 5\}$. Then \mathcal{F} is listed in the following table:

In Section 6 we make a general conjecture about the list of groups of order p^6 which support saturated fusion systems \mathcal{F} with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$.

Remark 5.6. The saturated fusion systems on SmallGroup(3^6 , 99) and SmallGroup(3^6 , 100) in Theorem 5.5 first alerted us to a mistake in the main result of [DRV07]. These fusion systems are the first in an infinite family constructed in [PS19].

5.4. Groups of order 3^7 .

Theorem 5.7. Suppose that \mathcal{F} is a saturated fusion system on a 3-group of order 3^7 with $O_3(\mathcal{F}) = 1$ and $\mathcal{F} = O^3(\mathcal{F})$. Then \mathcal{F} is isomorphic to one of the 88 saturated fusion systems listed in the following table:

group #	sec. rank	ab. ind. p?	<i># s.f.s</i>	reference	type	citation(s)

5.5. **Isolated results.** In this short section we mention some known results for which we have been able to provide computer verification.

The following pair of fusion systems was constructed in [HS]. We confirm that these examples are saturated.

Theorem 5.8 ([HS, Theorem A]). Suppose that S is a Sylow 3-subgroup of $PSp_4(9)$ and A = J(S)is the Thompson subgroup of S. There is an elementary abelian subgroup E of order 81 such that S = AE and a saturated fusion system \mathcal{F} on S in which A and E are \mathcal{F} -essential and $Aut_{\mathcal{F}}(A) \cong 2. PSL_3(4).2^2$ and $Aut_{\mathcal{F}}(E) \cong (8 \circ SL_2(9)).2 = SL_2(9).Q_8$. Moreover $O^3(\mathcal{F}) = \mathcal{F}$, $O_3(\mathcal{F}) = 1$ and $O^{3'}(\mathcal{F})$ has index 2 in \mathcal{F} .

[HS, Theorem A] indicates that there are several other saturated fusion systems \mathcal{F} on a Sylow 3-subgroup of $PSp_4(9)$ for which $O^3(\mathcal{F}) = \mathcal{F}$ and $O_3(\mathcal{F}) = 1$. Apart from examples realized by overgroups of $PSp_4(9)$ in its automorphism group, there are examples in which $\mathcal{E}_{\mathcal{F}} = \{E^S\}$ and examples in which $\mathcal{E}_{\mathcal{F}} = \{A\} \cup \{E^S\}$ and A is the 3-dimensional orthogonal module for $PSL_2(9)$ of order 3⁶. These latter examples were first constructed by Clelland–Parker in [CP10].

We have computationally verified the known theorems below.

Theorem 5.9 ([AOV17, Theorems 4.1, 4.3, 5.1]). All saturated fusion systems \mathcal{F} with $O_2(\mathcal{F}) = 1$ and $O^2(\mathcal{F}) = \mathcal{F} = O^{2'}(\mathcal{F})$ on 2-groups of order at most 2^8 are realizable.

For the execution of Theorem 5.9, we need to exploit [Oli13, Theorem B] to handle SmallGroup($2^8, 55683$) \cong Dih(8) \times Dih(8) $\times 2 \times 2$. As expected, our routine locates just four proto-essential subgroups, but these subgroups support a daunting 268435456 = 2^{28} automizer sequences.

Theorem 5.10 ([OV09, Theorem 7.8]). Suppose that \mathcal{F} is a saturated fusion system on a Sylow 2-subgroup S of Co₃ with $\mathcal{F} = O^2(\mathcal{F})$ and $O_2(\mathcal{F}) = 1$. Then $\mathcal{F} = \mathcal{F}_S(\text{Co}_3)$ or $\mathcal{F} = \text{Sol}(3)$ is the smallest Solomon 2-fusion system.

Theorem 5.11 ([PS18, Theorem 1.1]). Suppose that \mathcal{F} is a saturated fusion system on a Sylow 7-subgroup S of $G_2(7)$ with $O_7(\mathcal{F}) = 1$. Then \mathcal{F} is one of the 28 fusion systems listed in [PS18, Table 5.1] or $\mathcal{F}_S(G_2(7))$.

The saturated fusion systems \mathcal{F} with $O_p(\mathcal{F}) = 1$ on a Sylow *p*-subgroup *S* of $G_2(p)$ are determined in [PS18] where it is shown that for $p \geq 11$ only $\mathcal{F}_S(G_2(p))$ occurs. When $p \in \{5, 7\}$ there are, in addition, fusion systems realized by sporadic simple groups; when p = 7 we also obtain exotic examples. Theorems 5.5 and Theorem 5.11 give an independent confirmation of the calculations in [PS18] of all the exceptional cases when $p \leq 7$.

6. Concluding observations

In our examples, we observe that whenever \mathcal{F} is a saturated fusion system on a direct product $S = S_1 \times S_2$ with S_i non-abelian and $\mathcal{F} = O^{p'}(\mathcal{F})$, \mathcal{F} splits as a direct product $\mathcal{F}_1 \times \mathcal{F}_2$ with \mathcal{F}_i a fusion system on S_i . In [Oli13, Theorem A], Oliver considers saturated fusion systems on 2-groups $S = S_1 \times S_2$ where S_1 and S_2 are non-trivial and not decomposable as direct products. Provided, for $j \in \{1, 2\}$, $\Omega_1(Z(S_j)) \leq S'_j$ and S_{3-j} does not contain a subgroup isomorphic to $S_j \times S_j$, he demonstrates that a saturated fusion system \mathcal{F} on S with $\mathcal{F} = O^{2'}(\mathcal{F}) = O^2(\mathcal{F})$ decomposes as $\mathcal{F}_1 \times \mathcal{F}_2$ where \mathcal{F}_j is a saturated fusion system on S_j . If there is to be a generalization of Oliver's result to odd primes, then the following example indicates that one would need to impose additional hypotheses:

Example 6.1. Suppose that p is odd. A Sylow p-subgroup of $G = \text{Sym}(2p^2)$ is isomorphic to $S \cong p \wr p \times p \wr p$; however $\mathcal{F} = \mathcal{F}_S(G)$ is not it a direct product of two fusion systems each on $p \wr p$. Indeed, the base group E of S of order p^{2p} is elementary abelian and \mathcal{F} -essential with $\text{Aut}_{\mathcal{F}}(E) \cong (p-1) \wr \text{Sym}(2p)$ and as E does not contain either direct factor, this example shows that [Oli13, Lemma 1.11(b)] does not extend to any odd prime. We also remark that this is an example with $|\text{Out}_S(E)| > p$ and $O_{p'}(\text{Out}_{\mathcal{F}}(E))$ not centralized by $O^{p'}(\text{Out}_{\mathcal{F}}(E))$.

Next recall that in [Gra18], Grazian defines an \mathcal{F} -pearl of a saturated fusion system \mathcal{F} to be an \mathcal{F} -essential subgroup which is either of order p^2 or non-abelian of order p^3 . We have the following remark which pertains to \mathcal{F} -pearls and particularly to the fusion systems in A.5.21 to A.5.25. Suppose that S is a maximal class p-group. Then the 2-step centralizer is defined to be $\gamma_1(S) := C_S(S'/[S, S, S, S])$. Suppose that S has a self-centralizing subgroup P of order p^2 with $P \not\leq \gamma_1(S)$ and an element $\alpha \in \operatorname{Aut}(S)$ of order p-1 which leaves P invariant and induces an element of determinant 1 in $\operatorname{Aut}(P) \cong \operatorname{GL}_2(p)$. Form the fusion datum $\mathcal{D} = (\mathcal{Q}, \mathcal{A})$ with $\mathcal{Q} = (S, P), \mathcal{A}(S) = \langle \operatorname{Inn}(S), \alpha \rangle$ and $\mathcal{A}(P) = \operatorname{SL}_2(p)$. Then $\mathcal{F} = \mathcal{F}(\mathcal{D})$ is saturated with $O_p(\mathcal{F}) = 1$ and $\operatorname{foc}(\mathcal{F}) = [S, \alpha]$. A similar construction can be performed with non-abelian pearls. We speculate that many of the maximal class p-groups have such an automorphism [DE17]. Indeed, \mathcal{F} -pearls can be attached to any saturated fusion system on a maximal class p-group which has a class $P^{\mathcal{F}}$ of \mathcal{F} -centric elementary abelian subgroups of order p^2 under the described conditions.

We have the following theorem which is inspired by [Gra18, Lemma 3.7]:

Theorem 6.2. Suppose that \mathcal{F} is a saturated fusion system on S and E is an \mathcal{F} -essential subgroup which is not contained in any other \mathcal{F} -essential subgroup. Let $A = N_{\operatorname{Aut}_{\mathcal{F}}(S)}(E)$ and C be a complement to $N_{\operatorname{Inn}(S)}(E)$ in A. Define $S_1 = N_S(E)$ and, for i > 1, $S_i = N_S(S_{i-1})$. For $i \ge 1$, C leaves S_i invariant and induces $C_i \le \operatorname{Aut}(S_i)$. Define \mathcal{F}_i to be the fusion system on S_i given by $\langle \operatorname{Inn}(S_i)C_i, \operatorname{Aut}_{\mathcal{F}}(E) \rangle$. If no proper subgroup of E is S_1 -centric, then, for each $i \ge 1$, \mathcal{F}_i is saturated.

Proof. Suppose that $i \geq 1$. Since C leaves both S and S_1 invariant it also leaves each S_i invariant. Set $G_i = S_i \rtimes C_i$ and let $K = \operatorname{Out}_{G_i}(E)$ and $\Delta = \operatorname{Out}_{\mathcal{F}}(E)$. Then G_i, K and Δ satisfy the hypothesis of [BLO06, Proposition 5.1]. It follows that \mathcal{F}_i is saturated.

Example 6.3. We apply Theorem 6.2 to some of our examples and make further observations.

- (1) Let G = M be the monster finite simple group, $S \in \text{Syl}_7(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$. Then \mathcal{F} has an \mathcal{F} -pearl P of order 49 ([PS18, Theorem 5.1]). Hence Theorem 6.2 implies that there are saturated fusion systems \mathcal{F}_2 , \mathcal{F}_3 on groups S_2 and S_3 . As P is abelian, $O_7(\mathcal{F}_2) = O_7(\mathcal{F}_3) =$ 1. In fact we have $\mathcal{F}_2 = \mathcal{F}(7^4, 7, 1)$ and $\mathcal{F}_3 = \mathcal{F}(7^5, 37, 1)$ is the Grazian fusion system; both are exotic.
- (2) Let p be an odd prime, $G = \operatorname{PGL}_p(q)$ and $S \in \operatorname{Syl}_p(G)$ where $p \mid q-1$. Set $\mathcal{F} = \mathcal{F}_S(G)$. S is a maximal class group with a maximal abelian subgroup A < S and $\mathcal{E}_{\mathcal{F}} = \{A, P\}$ where

P is an \mathcal{F} -pearl of order p^2 . We are thus in a situation where Theorem 6.2 applies with E = P and we obtain a string of saturated fusion systems $\mathcal{F}_i \subseteq \mathcal{F}$ on p-groups S_i , all of which have an abelian subgroup of index p.

(3) Let \mathcal{F} be one of the exotic fusion systems in [PS15]. Then $|S| = p^{p-1}$ and we obtain saturated fusion systems \mathcal{F}_i , $2 \leq i \leq p-3$ on p-groups of order p^{i+2} . The group S has maximal class and has 2-step centralizer Q, an extraspecial subgroup of order p^{p-2} . We have $|S_i \cap Q| = p^{i+1}$ and this is abelian if and only if $i \leq (p-3)/2$. We speculate that almost all of the fusion systems \mathcal{F}_i are exotic.

Recall the definition of $H_{\mathcal{F}}(P)$ for P fully \mathcal{F} -normalized in S from the discussion before Lemma 3.13. The next two lemmas demonstrate that we can remove certain subgroups while preserving saturation.

Lemma 6.4. Suppose that \mathcal{F} is a saturated fusion system on S and P is an \mathcal{F} -essential subgroup of S. Let \mathcal{C} be a set of \mathcal{F} -conjugacy class representatives of \mathcal{F} -essential subgroups with $P \in \mathcal{C}$. Assume P has the minimality property:

if Q < P, then Q is not S-centric.

If $H_{\mathcal{F}}(P) \leq K \leq \operatorname{Aut}_{\mathcal{F}}(P)$, then

 $\mathcal{G} = \langle \operatorname{Aut}_{\mathcal{F}}(S), K, \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{C} \setminus \{P\} \rangle$

is saturated. Furthermore, P is \mathcal{G} -essential if and only if $K > H_{\mathcal{F}}(P)$ and in this case $\operatorname{Aut}_{\mathcal{G}}(P) = K$.

Proof. To prove that \mathcal{G} is saturated, it suffices to show that every \mathcal{G} -centric subgroup is \mathcal{G} -saturated. Let $T \leq S$ be \mathcal{G} -centric. Then the minimality property of P implies that $T^{\mathcal{G}} = T^{\mathcal{F}}$. In particular, it follows that the set of \mathcal{F} -centric subgroups coincides with the set of \mathcal{G} -centric subgroups.

As \mathcal{F} is saturated, there exists $R \in T^{\mathcal{F}}$ such that R is fully \mathcal{F} -automized and \mathcal{F} -receptive. Because $T^{\mathcal{F}} = T^{\mathcal{G}}$, $R \in T^{\mathcal{G}}$. Since $\operatorname{Aut}_{\mathcal{G}}(R) \leq \operatorname{Aut}_{\mathcal{F}}(R)$ and $\operatorname{Aut}_{\mathcal{S}}(R) \leq \operatorname{Aut}_{\mathcal{G}}(R)$, the fact that $\operatorname{Aut}_{\mathcal{S}}(R) \in \operatorname{Syl}_p(\operatorname{Aut}_{\mathcal{F}}(R))$ implies that $\operatorname{Aut}_{\mathcal{S}}(R) \in \operatorname{Syl}_p(\operatorname{Aut}_{\mathcal{G}}(R))$. Hence R is fully \mathcal{G} -automized.

Assume that $Q \in R^{\mathcal{F}} = R^{\mathcal{G}}$ and $\theta \in \operatorname{Hom}_{\mathcal{G}}(Q, R)$. As R is \mathcal{F} -receptive and $\theta \in \operatorname{Hom}_{\mathcal{F}}(Q, R)$, there exists an extension $\tilde{\theta} \in \operatorname{Hom}_{\mathcal{F}}(N_{\theta}, S)$. We need to show that some such $\tilde{\theta}$ can be found in $\operatorname{Hom}_{\mathcal{G}}(N_{\theta}, S)$. If $N_{\theta} = Q$, then we take $\tilde{\theta} = \theta \in \operatorname{Hom}_{\mathcal{G}}(N_{\theta}, S)$ and there is nothing further to do. Hence $N_{\theta} > Q$. If $|N_{\theta}| > |P|$, then $\tilde{\theta}$ is a product only of maps from $\operatorname{Aut}_{\mathcal{F}}(S)$ and $\operatorname{Aut}_{\mathcal{F}}(E)$ with $E \in \mathcal{C} \setminus \{P\}$ by the Alperin-Goldschmidt Theorem 2.4, and so $\tilde{\theta} \in \operatorname{Hom}_{\mathcal{G}}(N_{\theta}, S)$ in this case. Thus $|R| < |N_{\theta}| \leq |P|$. Assume that $\tilde{\theta} \notin \operatorname{Hom}_{\mathcal{G}}(N_{\theta}, S)$. Then $\tilde{\theta} = \alpha_1 \alpha_2$ where $\alpha_1 \in \operatorname{Hom}_{\mathcal{G}}(N_{\theta}, P)$ and $\alpha_2 \in \operatorname{Hom}_{\mathcal{F}}(N_{\theta}\alpha_1, S)$. In particular, $Q\alpha_1 < N_{\theta}\alpha_1 \leq P$. Thus the minimality of P now contradicts R being \mathcal{G} -centric. We deduce that $\tilde{\theta} \in \operatorname{Hom}_{\mathcal{G}}(N_{\theta}, S)$. Hence R is \mathcal{G} -receptive and this means that T is \mathcal{G} -saturated. Using [AKO11, Theorem I.3.10] we have that \mathcal{G} is saturated. As P is fully \mathcal{F} -normalized, by [AKO11, Proposition I.3.3 (b)] $H_{\mathcal{F}}(P) = \operatorname{Aut}_{\mathcal{G}}(P)$ if and only if P is not \mathcal{G} -essential.

Let

$$\mathcal{G}_0 = \langle \operatorname{Aut}_{\mathcal{F}}(S), H_{\mathcal{F}}(P), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{C} \setminus \{P\} \rangle = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) \mid E \in \mathcal{C} \setminus \{P\} \rangle.$$

Then \mathcal{G}_0 is saturated, P is not \mathcal{G}_0 -essential and $\operatorname{Aut}_{\mathcal{G}_0}(P) = H_{\mathcal{F}}(P)$. Assume that $K > H_{\mathcal{F}}(P)$. Then P is \mathcal{G} -essential. Suppose that $\theta \in \operatorname{Aut}_{\mathcal{G}}(P)$. Then θ is a composition of maps from $\operatorname{Aut}_{\mathcal{F}}(S)$, $\operatorname{Aut}_{\mathcal{F}}(E), E \in \mathcal{C} \setminus \{P\}$ and K. Thus

$$\theta = \kappa_1 \alpha_1 \kappa_2 \alpha_2 \dots$$

with $\kappa_i \in K$ and $\alpha_i \in \operatorname{Aut}_{\mathcal{G}_0}(P) = H_{\mathcal{F}}(P) \leq K$ and so $\theta \in K$. Hence $\operatorname{Aut}_{\mathcal{G}}(P) = K$.

Lemma 6.5. Assume that \mathcal{F} is a saturated fusion system on a p-group S, \mathcal{C} is a set of \mathcal{F} conjugacy class representatives of \mathcal{F} -essential subgroups, and $P \in \mathcal{C}$. If P is an \mathcal{F} -pearl, then $\mathcal{G} = \langle \operatorname{Aut}_{\mathcal{F}}(S), \operatorname{Aut}_{\mathcal{F}}(E) | E \in \mathcal{C} \setminus \{P\} \rangle$ is saturated.

Proof. If P is abelian, then Lemma 6.4 gives the result. Assume that P is extraspecial. We claim that P is not properly contained in any \mathcal{F} -essential subgroup. If p is odd, then this follows from [Gra18, Theorem 3.6]. If p = 2, then P is quaternion of order 8 and so $\operatorname{Aut}_{\mathcal{F}}(P) = \operatorname{Aut}(P) \cong$ $\operatorname{Sym}(4)$ and $|\operatorname{Out}_S(P)| = 2$ as P is \mathcal{F} -essential. In particular, $\operatorname{Aut}_{Z_2(S)}(P)$ is contained in the centre of $\operatorname{Aut}_S(P) \cong \operatorname{Dih}(8)$. Hence $Z_2(S) < P$ and so $Z_2(S)$ has order 4 and $|S : C_S(Z_2(S))| =$ 2. Let $x \in P \setminus Z_2(S)$. Then $x \notin C_S(Z_2(S))$ and $C_S(x) \cap C_S(Z_2(S)) = C_S(P) = Z(S)$. As $|S : C_S(Z_2(S))| = 2$ and |Z(S)| = 2, it follows that $|C_S(x)| = 4$. Now [GLS96, Lemmas 10.24 and 10.25] imply that S is either quaternion or semidihedral. Since P is non-abelian, any proper subgroup which properly contains P is quaternion of order at least 16. Such groups cannot be \mathcal{F} -essential as their automorphism groups are 2-groups.

Suppose that T is \mathcal{G} -centric. Assume $T^{\mathcal{G}}$ does not contain a proper subgroup of P. Then $T^{\mathcal{F}} = T^{\mathcal{G}}$ and we know $\operatorname{Aut}_{\mathcal{G}}(T) = \operatorname{Aut}_{\mathcal{F}}(T)$ so long as $P \notin T^{\mathcal{G}}$. In particular, $\operatorname{Aut}_{\mathcal{G}}(R) = \operatorname{Aut}_{\mathcal{F}}(R)$ for R > Tand hence the \mathcal{G} -surjectivity property holds for T. Therefore we may and do assume that T < P. Thus $|T| = p^2$ and, as T is \mathcal{G} -centric, $C_S(T) = T$, $P = N_S(T)$ and T is fully \mathcal{G} -normalized. Since P is \mathcal{F} -essential, T is \mathcal{F} -conjugate to $Z_2(S)$ and so T is not fully \mathcal{F} -normalized and in particular is not \mathcal{F} -essential. In addition, as $P = N_S(T) = TZ_2(S)$, the only \mathcal{F} -essential subgroup containing T is P. Indeed, if E > T is \mathcal{F} -essential, then $P = N_S(T) \ge N_E(T) > T$ and so $P = N_E(T) \le E$. As P is not properly contained in any \mathcal{F} -essential subgroup, we conclude that P = E. Hence

$$\operatorname{Aut}_{\mathcal{G}}(T) = \{ \phi |_T \mid \phi \in N_{\operatorname{Aut}_{\mathcal{F}}(S)}(T) \}.$$

Furthermore, for $\phi \in N_{\operatorname{Aut}_{\mathcal{F}}(S)}(T)$, we have

$$P\phi = \langle T\phi, Z_2(S)\phi \rangle = \langle T, Z_2(S) \rangle = P$$

It follows that the restriction map $N_{\operatorname{Aut}_{\mathcal{G}}(P)}(T) \to N_{\operatorname{Aut}_{\mathcal{G}}(T)}(\operatorname{Aut}_{P}(T))$ is a surjection. In particular, T has the \mathcal{G} -surjectivity property and so we conclude that \mathcal{G} is saturated by Theorem 2.3.

Example 6.6. Let $G = E_8(2)$, $S \in \text{Syl}_5(G)$ and $\mathcal{F} = \mathcal{F}_S(G)$. Then $\mathcal{F} = \mathcal{F}(5^5, 30, 20)$ and the \mathcal{F} conjugacy classes of \mathcal{F} -essential subgroups have representatives A, which is elementary abelian, E_0 and E_1 which are extraspecial of order 5^3 and exponent 5. We have $\text{Out}_{\mathcal{F}}(A) \cong (4 \circ 2^{1+4}_+)$. Sym(6) which is isomorphic to the complex reflection group G_{31} . As a Sylow 5-subgroup $\text{Aut}_S(A)$ of $\text{Aut}_{\mathcal{F}}(A)$ is cyclic, the strongly *p*-embedded subgroup H_A of $\text{Aut}_{\mathcal{F}}(A)$ is just the normalizer of $\text{Aut}_S(A)$. The over-groups in G_{31} of H_A are $4 \circ 2^{1+4}_+$. Sym(5)_a, $4 \circ 2^{1+4}_+$. Sym(5)_b, $4 \circ 2^{1+4}_+$: Frob(20), $\text{GL}_2(5)$ acting (2/2) (acting with two non-trivial composition factors on A), $4 \times \text{Sym}(5)$ one acting (3/1) the other (1/3) H_A and $\text{Aut}_{\mathcal{F}}(A)$. Our stipulation that the fusion systems has no normal 5-subgroup then delivers, by Lemma 6.4 (we say "pruning" at A) fusion systems $\mathcal{F}(5^5, 30, 15)$, $\mathcal{F}(5^5, 30, 17)$, $\mathcal{F}(5^5, 30, 18)$, $\mathcal{F}(5^5, 30, 19)$ and $\mathcal{F}(5^5, 30, 21)$. The remaining two systems $\mathcal{F}(5^5, 30, 16)$ and $\mathcal{F}(5^5, 30, 22)$ cannot be obtained in this way and we see that $\mathcal{F}(5^5, 30, 22)$ prunes to give $\mathcal{F}(5^5, 30, 16)$. Since E_0 and E_1 are extraspecial, Lemma 6.5 applies and E_0 as well as E_1 can also be pruned individually and together. This gives the fusion systems $\mathcal{F}(5^5, 30, 33)$ through $\mathcal{F}(5^5, 30, 48)$. In this way we see how a group fusion system can be pruned to deliver a plethora of exotic systems and explain many of the systems that appear on a given group.

Together, Theorem 6.2, and Lemmas 6.4 and 6.5 allow us to construct new saturated fusion systems from fusion systems of groups.

Based on the computations in this paper and observations about local structure in finite simple groups, we make the following conjecture:

Conjecture 1. Suppose that $p \ge 5$, S is a p-group of order p^6 and \mathcal{F} is a saturated fusion system on S with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. Then either S has maximal class or S is a Sylow subgroup of $PSL_3(p) \times PSL_3(p)$, $PSL_3(p^2)$, $PSL_4(p)$ or $PSU_4(p)$. Furthermore, if $p \ge 11$ and S has maximal class, then either S is a Sylow p-subgroup of $G_2(p)$ or S has an abelian subgroup of index p (perhaps even $S \cong B(p, 6; 0, 0, 0, 0)$) and \mathcal{F} is obtained by pruning one of the fusion systems in [CP10] which has $Aut_{\mathcal{F}}(\gamma_1(S)) \cong PSL_2(p)$ acting irreducibly on $\gamma_1(S)$.

To prove the first part of Conjecture 1, by the results of the present paper we may assume that $p \geq 7$. We may also assume that S has no abelian subgroup of index p and by [Gra19, Theorem C] that the sectional rank of S is at least 4. By [Mon18], we can also assume that S does not have an extraspecial subgroup of index p as otherwise S is one of the groups listed. By [Gra18, Lemma 1.5], we may assume that \mathcal{F} has no \mathcal{F} -pearls, for otherwise S has maximal class. If E is \mathcal{F} -essential and $|\operatorname{Out}_S(E)| \geq p^2$, then Lemma 4.7 implies that E is elementary abelian of order p^4 , is normal in S and $|\operatorname{Out}_S(E)| = p^2$. Since a Sylow p-subgroup of $\operatorname{GL}_4(p)$ has exponent p, this leads to $O^{p'}(\operatorname{Aut}_{\mathcal{F}}(E)) \cong \operatorname{SL}_2(p^2)$ or $\operatorname{PSL}_3(p^2)$ and in the second that S is isomorphic to a Sylow p-subgroup of $\operatorname{PSU}_4(p)$. Hence $|\operatorname{Out}_S(E)| = p$ for all \mathcal{F} -essential subgroups E of \mathcal{F} .

To prove the second part of Conjecture 1, results in preparation by Grazian and Parker [GP20] show that, provided S is not isomorphic to the Sylow p-subgroup of $G_2(p)$, the \mathcal{F} -essential subgroups are either \mathcal{F} -pearls or perhaps $\gamma_1(S)$. Furthermore, if $\gamma_1(S)$ is non-abelian, then the \mathcal{F} essential subgroups are all abelian \mathcal{F} -pearls. So this part of the conjecture boils down to an inspection of the isomorphism types of maximal class p-groups with an abelian maximal subgroup which support a fusion system, and the determination of the maximal class p-groups which support a fusion system with an abelian \mathcal{F} -pearl.

The fusion systems listed in Tables 20 and 22 show that the second part of the conjecture does not hold when p = 5. In fact the table in Theorem 5.5 could lead us to speculate that the Blackburn groups B(p, 6; 0, 0, i, 0) and B(p, 6; 0, 1, i, 0) where $0 \le i \le p - 1$ all support saturated fusion systems with $O_p(\mathcal{F}) = 1$ and $O^p(\mathcal{F}) = \mathcal{F}$. However, we don't believe this is the case even when p = 7. We have computed that the maximal class 7-groups which have a saturated fusion system \mathcal{F} with an abelian \mathcal{F} -pearl are B(7, 6; 0, 0, 0, 0) and the Sylow 7-subgroup of $G_2(7)$. For p = 7, the group fusion system on $PSL_7(8)$ on one of its Sylow 7-subgroups cannot be obtained from one of the systems in [CP10]. This is the origin of the assumption that $p \ge 11$.

We make the following conjecture concerning Lie type groups in their defining characteristic:

Conjecture 2. Suppose that p is a prime and S is the collection of pairs (G, S) where G is a simple Lie type group defined in characteristic p which is not isomorphic to $PSp_4(p^a)$ and $S \in Syl_p(G)$. Then, for all but finitely many exceptions, if $(G, S) \in S$ and \mathcal{F} is a saturated fusion system on S with $O_p(\mathcal{F}) = 1$, then $\mathcal{F} = \mathcal{F}_S(H)$ for some $G \leq H \leq Aut(G)$.

To prove Conjecture 2 we can assume that both the rank of G and the field are large, although it would be desirable to have a complete list of exceptions.

The work of Henke–Shpectorov [HS] and Clelland–Parker [CP10] shows that for p odd the Sylow p-subgroup of $PSp_4(p^n)$ supports exotic fusion systems, and so this restriction is required in Conjecture 2. All the other known sporadic groups or exotic fusion systems on such p-groups only occur for small values of p. For example, the conjecture holds if $G = G_2(p)$, $PSU_4(p)$, $SL_3(p^n)$ by [PS18, Mon18, Cle07]. For $q = p^n > p$, Conjecture 2 holds for $U_4(q)$ and $G_2(q)$ by work of van Beek [vB22]. Further, evidence for the validity of Conjecture 2 is provided by [Ono11, PPSS19].

APPENDIX A. A COMPENDIUM OF SATURATED FUSION SYSTEMS ON SMALL *p*-groups of ODD order

Throughout this appendix p is odd. We give detailed descriptions of all the fusion systems appearing in Theorems 5.1, 5.2, 5.5 and 5.7.

A.1. Notation. Here we introduce some notational conventions to describe fusion systems on certain families of groups.

Suppose first that S is p-group which possesses a unique abelian subgroup A of index p and let \mathcal{F} be a saturated fusion system on S. Define $A_0 = Z(S)[S, S]$. Assuming that $|Z(S) \cap [S, S]| = p$, by [COS17, Lemma 2.2(d)] we have $|A : A_0| = p$ and we may choose $\mathbf{a} \in A \setminus A_0$ and $\mathbf{x} \in S \setminus A$ so that $A_0 \langle \mathbf{x} \rangle$ and $[S, S] \langle \mathbf{a} \rangle$ are each normalized by $\operatorname{Aut}_{\mathcal{F}}(S)$. We may also choose \mathbf{x} to have order p if some element of $S \setminus A$ does. For each $i = 0, 1, \ldots, p - 1$ we set (cf. [COS17, Notation 2.4]):

$$V_i = Z(S) \langle \mathbf{x} \mathbf{a}^i \rangle$$
 and $E_i = Z_2(S) \langle \mathbf{x} \mathbf{a}^i \rangle$.

We adopt similar conventions when S is a maximal class p-group. The metabelian p-groups of maximal class r-1 which satisfy $[\gamma_1(S), \gamma_2(S)] \leq \gamma_{r-2}(S)$ have been classified by Blackburn in [Bla58, Section 4, pages 82, 83]. For $r \geq 4$, and $\alpha, \beta, \gamma, \delta \in \{0, 1, 2, \ldots, p-1\}$, define

$$B(p,r;\alpha,\beta,\gamma,\delta) = \langle s, s_1, \dots, s_{r-1} \mid \mathbf{R1}, \mathbf{R2}, \mathbf{R3}, \mathbf{R4}, \mathbf{R5}, \mathbf{R6}, \mathbf{R7} \rangle$$

where, defining $s_r = s_{r+1} = \cdots = s_{r+p-2} = 1$, the relations are as follows:

R1: $s_i = [s_{i-1}, s]$ for $i \in \{2, ..., r\}$; **R2**: $[s_1, s_2] = s_{r-2}^{\alpha} s_{r-1}^{\beta}$; **R3**: $[s_1, s_3] = s_{r-1}^{\alpha}$; **R4**: $[s_1, s_i] = 1$ for $i \in \{4, ..., r-1\}$; **R5**: $s^p = s_{r-1}^{\delta}$; **R6**: $s_1^p s_2^{\binom{p}{2}} s_3^{\binom{p}{3}} \cdots s_p = s_{r-1}^{\gamma}$; **R7**: $s_i^p s_{i+1}^{\binom{p}{2}} s_{i+2}^{\binom{p}{3}} \cdots s_{i+p-1} = 1$ for $i \in \{2, ..., r-1\}$. In this case, for $i \in \{0, 1, 2, ..., p-1\}$, we set:

$$V_i = \langle ss_1^i, s_{r-1} \rangle$$
 and $E_i = \langle ss_1^i, s_{r-2}, s_{r-1} \rangle$.

Note that we may take $\mathbf{x} = s$ and $\mathbf{a} = s_1$ when $\langle s_1, s_2 \dots s_{r-1} \rangle$ is abelian. For maximal class *p*-groups *S*, we define $\gamma_2(S) = [S, S]$ and for $j \geq 3$, $\gamma_j(S) = [\gamma_{j-1}(S), S]$. The subgroup $\gamma_1(S)$ defined by $C_S(\gamma_2(S)/\gamma_4(S))$ is a 2-step centralizer. In [Bla58] Blackburn provides presentations for metabelian *p*-groups *S* of maximal class r - 1 which satisfy $[\gamma_1(S), \gamma_2(S)] \leq \gamma_{r-2}(S)$. Especially, he gives a complete classification of all maximal class 3-groups and all maximal class groups of order at most p^6 .

As the size of $\operatorname{Out}_{\mathcal{F}}(S)$ grows, some of the subgroups become \mathcal{F} -conjugate. We indicate that X and Y are \mathcal{F} -conjugate by $X \sim_{\mathcal{F}} Y$.

In the description of the groups in our tables, we use the following notation which is similar to that given in [CCN⁺85]. The symmetric group of degree n is Sym(n), and Alt(n) is the corresponding alternating group. We denote by Frob(20) the Frobenius group of order 20, Dih(n)and SDih(n) are the dihedral and semidihedral groups of order n and, for r a natural number, r^n represents the homocyclic r-group of order r^n with n suppressed if the group is cyclic. For the classical groups we use standard notation so for example PSU₅(4) is the projective special unitary group in dimension 5 defined over the field of order 16. The groups 2^{1+4}_+ and 2^{1+4}_- are the extraspecial 2-groups of order 32, the first one of plus type the second of minus type. By PFU₅(4) we include the group of field automorphisms on PGU₅(4) (which contributes a cyclic group of order 4). The notation for the sporadic simple groups is standard. For extensions and quotients we have the following conventions. The group $X = A \cdot B$ is a non-split extension with normal subgroup A and $X/A \cong B$. The group X = A:B is the split extension and A.B is an extension of undetermined type. We write $A \wr B$ for the wreath product of A by B normally with transparent action. By $A \circ B$ we represent the central product of A and B. Thus $4 \circ 2^{1+4}_+ \cong 4 \circ 2^{1+4}_-$ has centre of order 4. By $\frac{1}{n}A$ we mean an unspecified subgroup of index n in A. From time to time we meet groups with the same outward appearance and we indicate that they are non-isomorphic by introducing subscripts. For example the complex reflection group $G_{31} \cong (4 \circ 2^{1+4}_+)$. Sym(6) has two non-isomorphic subgroups with shape $(4 \circ 2^{1+4}_+)$. Sym(5). We denote one by $(4 \circ 2^{1+4}_+)$. Sym(5)_a and the other $(4 \circ 2^{1+4}_+)$. Sym(5)_b. For automorphism groups of PSU₄(3), we have followed ATLAS [CCN⁺85] conventions.

In the first column of every table is a number j which allows us to specify a fusion system $\mathcal{F}(p^n, i, j)$ on SmallGroup (p^n, i) . The last column indicates whether or not a particular fusion system is exotic. Mostly this is completed with reference to a citation listed in the final column of the appropriate table in Section 5. To describe the exotic fusion systems discovered in [DRV07, Theorem 5.10], we use the notation $\mathcal{F}_{\text{DRV}}(3^n, i)$ to refer to the fusion system called $\mathcal{F}(3^n, i)$ in that paper. When $|S| = 3^7$, we have fusion systems on direct products $S = S_1 \times S_2$ where $S_1 \cong 3^{1+2}$ and S_2 is a Blackburn group, and one of the direct factors can support an exotic fusion system. In these cases, computer calculations reveal that S_1 and S_2 are strongly closed in \mathcal{F} . Hence [AKO11, Proposition I.6.7] implies that the projections \mathcal{F}_1 and \mathcal{F}_2 on S_1 and S_2 are saturated with \mathcal{F} isomorphic to a subfusion system of $\mathcal{F}_1 \times \mathcal{F}_2$. Furthermore, we obtain $O^p(\mathcal{F}_i) = \mathcal{F}_i$ and $O_p(\mathcal{F}_i) = 1$ for i = 1, 2 and so all our examples can be constructed from smaller cases listed in our tables. Notice that if $\mathcal{F} = \mathcal{F}_S(G)$ for some finite group G then $N_{\mathcal{F}}(S_1) = \mathcal{F}_S(N_G(S_1))$ and $\mathcal{F}_2 \cong \mathcal{F}_{S/S_1}(N_G(S_1)/S_1)$. In particular, if \mathcal{F}_2 is exotic, then \mathcal{F} is exotic.

A.2. Groups of order p^3 . We start with possibly the most well-known result in the subject of fusion systems. If S is a non-abelian p-group of order p^3 which supports a saturated fusion system \mathcal{F} with $O_p(\mathcal{F}) = 1$, then S is extraspecial of exponent p. The fusion systems are described in the celebrated paper by Ruiz and Viruel [RV04, Tables 1.1 and 1.2]. Famously, there are three exotic systems on the group of order 7^3 .

A.3. Groups of order p^4 . By Theorem 5.1, S has an abelian subgroup of index p so we may adopt the notation of Section A.1. We give detailed descriptions of the fusion systems on these groups.

A.3.1. **SmallGroup** $(3^4, 7)$. This group is isomorphic to a Sylow 3-subgroup of Alt(9).

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example(s)

TABLE 5. Saturated fusion systems on a Sylow 7-subgroup of $PSp_4(7)$

A.4. Groups of order p^5 . By Corollary 5.3 if S is not isomorphic with SmallGroup(7^5 , 37), then it has an abelian subgroup of index p and we may adopt the notation of Section A.1.

A.4.1. **SmallGroup**(3^5 , 26). This is group B(3, 5; 0, 0, 0, 0) which is isomorphic to a Sylow 3subgroup of PGU₃(8). Where appropriate, we indicate in the Example column how these fusion systems correspond to the exotic examples discovered in [DRV07, Theorem 5.10, Table 6]. Here we point out a small error: $\mathcal{F}(3^5, 26, 3)$ is exotic, but labelled $3^3D_4(2)$ in [DRV07, Theorem 5.10, Table 6].

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(E_1)$	$\operatorname{Out}_{\mathcal{F}}(E_2)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	$\operatorname{GL}_2(3)$	—	$\operatorname{GL}_2(3)$	$SL_2(3)$	$E_1 \sim_{\mathcal{F}} E_2$	2×2	${}^{2}\mathrm{F}_{4}(8)$

9	$2 \times \text{Sym}(5)$	$2 \times \mathrm{GL}_2(3)$	—	$2 \times 2 \times 2$	—

TABLE 7. Saturated fusion systems on a Sylow 3-subgroup of Alt(12)

A.4.3. **SmallGroup** $(5^5, 30)$. This group is isomorphic to a Sylow 5-subgroup S of PGU₅(4). It has maximal class and has unique subgroup A of index 5 so that the notation in Section A.1 applies.

We make some remarks concerning the 5-fusion system \mathcal{F} of $E_8(2)$. Setting Z = Z(S), $\mathcal{G} = C_{\mathcal{F}}(Z)$ is isomorphic to the 5-fusion system of $SU_5(4)$. Any \mathcal{G} -essential subgroup is \mathcal{F} -centric and it follows that \mathcal{F} is $\mathcal{F}(5^5, 30, 20)$ in Table 8 (note also that $Aut_{\mathcal{F}}(A) \cong (4 \circ 2^{1+4}_+)$. Sym(6) is isomorphic to the complex reflection group G_{31} in the standard Shephard-Todd enumeration.)

A.4.4. **SmallGroup**(7^5 , 32). The group **SmallGroup**(7^5 , 32) has maximal class and has a unique abelian subgroup of order 7^4 which is denoted A. It is isomorphic to the quotient of a Sylow 7-subgroup of $G_2(7)$ by its centre from which we recognise it as a Sylow 7-subgroup of $A : SL_2(7)$ where $SL_2(7)$ acts irreducibly on A as the symmetric cube of the natural $SL_2(7)$ -module.

TABLE 9. Saturated fusion systems on a Sylow 7-subgroup of 7^4 : SL₂(7)

A.4.5. **SmallGroup**(7⁵, 37). This is the maximal class group S = B(7, 5; 0, 1, 0, 0) and the notation in Section A.1 applies. S is isomorphic to a maximal subgroup of a Sylow 7-subgroup of G₂(7) which is not a unipotent radical subgroup of G₂(7). There is a single reduced fusion system $\mathcal{F}(7^5, 37, 1)$ on S, originally discovered by Grazian [Gra18]. This fusion system can be constructed from the Monster finite simple group using Theorem 6.2 (see Example 6.3(1).)

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	$SL_2(7)$	6	_

TABLE 10. Saturated fusion systems on the group B(7,5;0,1,0,0)

A.5. Groups of order p^6 . We describe *p*-fusion systems on *p*-groups of order p^6 when $p \in \{3,5\}$. By Theorem 5.5, we may adopt the notation of Section A.1 provided S is not isomorphic with SmallGroup($3^6, i$) for $i \in \{149, 307, 321, 453, 469\}$ or SmallGroup($5^6, i$) for $i \in \{240, 276, 609, 616, 643\}$ as these groups have no abelian subgroup of index 3 or 5 respectively.

A.5.1. **SmallGroup**(3^6 , 95). This is the maximal class group B(3, 6; 0, 0, 0, 0). It is isomorphic to a Sylow 3-subgroup of PSL₃(109). Where appropriate, we indicate in the Example column how these fusion systems correspond to the exotic examples discovered in [DRV07, Theorem 5.10, Table 4].

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(V_1)$	$\operatorname{Out}_{\mathcal{F}}(V_2)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example

2	$\operatorname{GL}_2(3)$	$Q_1 \sim_{\mathcal{F}} Q_2$	$\mathrm{Dih}(8)$	$G_2(3).2$

A.5.7. **SmallGroup**(3^6 , 307). This group is isomorphic to a Sylow 3-subgroup of PSL₄(3). We label the three unipotent radicals of proper parabolic subgroups in this group by Q_1, Q_2, Q_3 . The fusion systems are listed in Table 17. The group in the line of $\mathcal{F}(3^6, 307, 8)$ of shape $(4 \circ \text{SL}_2(5)).2$ has centre of order 2 and, in particular, is not isomorphic to GL₂(5).

TABLE 17. Saturated fusion systems on a Sylow 3-subgroup of $PSL_4(3)$

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(Q_1)$	$\operatorname{Out}_{\mathcal{F}}(Q_2)$	$\operatorname{Out}_{\mathcal{F}}(Q_3)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example

A.5.8. **SmallGroup**(3^6 , 321). This group is isomorphic to a Sylow 3-subgroup of PSU₄(3) $\cong \Omega_6^-(3)$. It is also a Sylow 3-subgroup of the semi-direct product Q: Alt(6) where $Q \cong 3^4$ is identified with the heart of the natural module (a 1-space stabilizer in the natural action of $\Omega_6^-(3)$ on its natural module). If $\mathcal{F} = O^3(\mathcal{F})$ and $O_3(\mathcal{F}) = 1$, there are always two classes of essential subgroups given by $\{Q, R\}$ where $R \cong 3^{1+4}_+$ is the unique extraspecial subgroup of S of index 3.

These are unipotent radicals of maximal parabolic subgroups if $PSU_4(3)$. The fusion systems on this group were determined in [BFM19].

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(Q)$	$\operatorname{Out}_{\mathcal{F}}(R)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	Alt(6)	$2.\mathrm{Sym}(4)$	4	$PSU_4(3)$
2	$\operatorname{Sym}(6)$	$GL_{2}(3).2$	$\mathrm{Dih}(8)$	$PSU_4(3).2_2$
3	$\operatorname{Sym}(6)$	$(Q_8 \times Q_8)$. Sym(3)	$\mathrm{Dih}(8)$	$PSU_6(2)$
4	$2 \times \text{Alt}(6)$	$2.\mathrm{Sym}(4):2$	2×4	$PSU_4(3).2_1$
5	M_{10}	$SL_2(3).2^2$	Q_8	$PSU_{4}(3).2_{3}$
6	M_{10}	$2.\mathrm{Sym}(5)$	Q_8	McL
7	$2 \times \text{Sym}(6)$	$(\mathbf{Q}_8 \times \mathbf{Q}_8).D_{12}$	$2 \times \text{Dih}(8)$	$\mathrm{PSU}_6(2).2$
8	$2 \times \text{Sym}(6)$	$GL_2(3).2^2$	$2 \times \text{Dih}(8)$	$PSU_4(3).2^2_{122}$
9	$2 \times M_{10}$	$SL_{2}(5).2^{2}$	$2 \times Q_8$	McL.2
10	$2 \times M_{10}$	$2.\mathrm{Sym}(4):2^2$	$2 \times Q_8$	$PSU_4(3).2^2_{133}$
11	Alt(6):4	$\mathrm{GL}_2(3):4$	2×8	$PSU_4(3).4$
12	Alt(6). Dih(8)	2^{1+4}_{-} . Sym(5)	$2 \times \text{SDih}(16)$	Co_2
13	Alt(6). Dih(8)	$\operatorname{SL}_2(3) \circ \operatorname{SDih}(16)$	$2 \times \text{SDih}(16)$	$PSU_4(3).Dih(8)$

TABLE 18. Saturated fusion systems on a Sylow 3-subgroup of $PSU_4(3)$

A.5.9. **SmallGroup**(3⁶, 453). This group is isomorphic with a Sylow 3-subgroup S of $G \times G$ where $G = PSL_3(3)$. Also set $H = {}^2F_4(2)'$. We have $Out(G \times G) \cong Out(H \times H) \cong Dih(8)$ and $Out(G \times H) \cong C_2 \times C_2$. The fusion systems on this group are one-to-one correspondence with classes of subgroups of these outer automorphism groups and are not individually listed.

A.5.10. **SmallGroup**(3^6 , 469). This group is isomorphic to a Sylow 3-subgroup of $G = PSL_3(9)$. We have $Out(G) \cong C_2 \times C_2$ and there are five fusion systems and they are realized in the appropriate subgroup by subgroups of $Aut(PSL_3(9))$ containing $PSL_3(9)$. This result agrees with one of the main theorems in Clelland's PhD thesis [Cle07, Theorem 4.5.1].

A.5.11. **SmallGroup** $(3^{6}, 479)$. This group is isomorphic with a Sylow 3-subgroup of Alt(15).

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example			
1	$\frac{1}{2}(2\wr \operatorname{Sym}(5))$	$4:\mathrm{GL}_2(3)$	—	$2 \times \text{Dih}(8)$	Alt(15)			
2	$\frac{1}{2}(2\wr \operatorname{Sym}(5))$	—	$2^2 : GL_2(3)$	$2 \times \text{Dih}(8)$	$\Omega^{10}(2)$			
3	$2\wr \mathrm{Sym}(5)$	—	$\operatorname{GL}_2(3) \times \operatorname{Dih}(8)$	$2 \times 2 \times \text{Dih}(8)$	$\Omega_{10}^{-}(2).2, \mathrm{Sp}_{10}(2)$			
4	$2\wr \mathrm{Sym}(5)$	$\operatorname{GL}_2(3) \times \operatorname{Dih}(8)$	—	$2 \times 2 \times \text{Dih}(8)$	$\operatorname{Sym}(15)$			

TABLE 19. Saturated fusion systems on a Sylow 3-subgroup of Alt(15)

A.5.12. **SmallGroup**(5^6 , 240). This group is isomorphic to $S_1 \times S_2$ where $S_1 \cong S_2 \cong 5^{1+2}_+$. We obtain fusion systems from conjugacy classes of subgroups of Out(Th × Th), Out(PSL₃(5) × Th) and Out(PSL₃(5) × PSL₃(5)) of which there are 2, 2 and 8. This accounts for all fusion systems and they are not individually listed.

A.5.13. **SmallGroup**(5^6 , 276). This group is isomorphic to a Sylow 5-subgroup of PSL₃(25), and the fusion systems are in bijection with classes of subgroups of Out(PSL₃(25)) \cong Dih(12). They are realized by subgroups of Aut(PSL₃(25)) containing PSL₃(25). This agrees with [Cle07].

A.5.14. **SmallGroup**(5^6 , 609). This group is isomorphic to a Sylow 5-subgroup of PSL₄(5) and the fusion systems are in bijection with classes of subgroups of Out(PSL₄(5)) \cong Dih(8).

A.5.15. **SmallGroup**(5^6 , 616). This group is isomorphic to a Sylow 5-subgroup of PSU₄(5) and the fusion systems are in bijection with classes of subgroups of Out(PSU₄(5)) $\cong C_2 \times C_2$.

A.5.16. **SmallGroup** $(5^6, 630)$. This is B(5, 6; 0, 0, 0, 0), it has an elementary abelian maximal subgroup A. The fusion systems are listed below:

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example

A.5.22. **SmallGroup**(5⁶, 639). This is B(5, 6; 0, 1, 1, 0). S is a maximal class group with nonabelian maximal subgroups, $\gamma_1(S) = C_S(Z_2(S))$ has nilpotency class 2 and $|Z(\gamma_1(S))| = 5^3$. The fusion system is described in Table 23 and is exotic.

A.5.23. **SmallGroup**(5⁶, 640). This is B(5, 6; 0, 1, 2, 0). S is a maximal class group with nonabelian maximal subgroups, $\gamma_1(S) = C_S(Z_2(S))$ has nilpotency class 2 and $|Z(\gamma_1(S))| = 5^3$. The fusion system is described in Table 23 and is exotic.

A.5.24. **SmallGroup**(5⁶, 641). This is B(5, 6; 0, 1, 3, 0). *S* is a maximal class group with nonabelian maximal subgroups, $\gamma_1(S) = C_S(Z_2(S))$ has nilpotency class 2 and $|Z(\gamma_1(S))| = 5^3$. The fusion system is described in Table 23 and is exotic.

A.5.25. **SmallGroup**(5⁶, 642). This is B(5, 6; 0, 1, 4, 0). S is a maximal class group with nonabelian maximal subgroups, $\gamma_1(S) = C_S(Z_2(S))$ has nilpotency class 2 and $|Z(\gamma_1(S))| = 5^3$. The fusion system is described in Table 23 and is exotic.

A.5.26. **SmallGroup**(5^6 , 643). This group is isomorphic to a Sylow 5-subgroup of G₂(5). It has maximal nilpotency class. The fusion systems were determined in [PS18, Theorem 7.2] and we take our notation from there. Hence Q and R are the unipotent radicals of the maximal parabolic subgroups containing S with Q extraspecial.

TABLE 24. Saturated fusion systems on a Sylow 5-subgroup of $G_2(5)$

A.6. Groups of order 3⁷. This subsection catalogues the fusion systems on groups of order 3⁷. As always we use our standard notation for groups of maximal class.

A.6.1. **SmallGroup**($3^7, 366$). This group is a Sylow 3-subgroup of $PSU_4(8)$ is isomorphic to the wreath product $9 \wr 3$. It has an abelian subgroup A of index 3 which is homocyclic. We have $E_0 \cong 9 \circ 3^{1+2}_+$.

TABLE 25. Saturated fusion systems on a Sylow 3-subgroup of $PSU_4(8)$

${\mathcal F}$	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example

2	$2 \wr \operatorname{Sym}(3)$	$\operatorname{GL}_2(3)$	2×2	$\mathrm{PSU}_4(8).2$

A.6.2. **SmallGroup**(3^7 , 386). This is the maximal class group B(3, 7; 0, 0, 0, 0). It is isomorphic to a Sylow 3-subgroup of PSU₃(53) and has an abelian subgroup A of index 3. Again, we indicate in the Example column how these fusion systems correspond to the exotic examples discovered in [DRV07, Table 6]. As in Section A.4.1, the fusion system $\mathcal{F}(3^7, 386, 4)$ is exotic and so incorrectly labelled in [DRV07, Table 6].

TABLE 26. Saturated fusion systems on a Sylow 3-subgroup of $PSU_3(53)$

${\mathcal F}$	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(V_0)$	$\operatorname{Out}_{\mathcal{F}}(E_0)$	$\operatorname{Out}_{\mathcal{F}}(E_1)$	$\operatorname{Out}_{\mathcal{F}}(E_2)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example

A.6.3. **SmallGroup**(3^7 , 2007). This group is isomorphic to a Sylow 3-subgroup S of both the Suzuki and Lyons sporadic simple groups. This group has a unique elementary abelian subgroup of order 3^5 and it is therefore characteristic in S. Taking $R = \langle x \mid x \in S \setminus A, x^3 = 1 \rangle$, we find R

has index 3 in S and is also characteristic. In the fusion systems, the essential subgroups are A and R.

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(R)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	M_{11}	2^{1+4}_{-} . Sym(3)	$\mathrm{SDih}(16)$	Suz
2	$2 \times M_{11}$	$(Q_8 \circ 2 \cdot Alt(5)).2$	$2 \times \text{SDih}(16)$	Ly
3	$2 \times M_{11}$	2^{1+4}_{-} . Dih(12)	$2 \times \text{SDih}(16)$	$\operatorname{Aut}(\operatorname{Suz})$

TABLE 27. Saturated fusion systems on a Sylow 3-subgroup of Suz

A.6.4. **SmallGroup**($3^7, 8705$). This group is isomorphic to $S_1 \times S_2$ where $S_1 \in \text{Syl}_3(\text{PSL}_3(3))$ and $S_2 \in \text{Syl}_3(\text{PSp}_4(3))$. As S_1 supports 4 fusion systems with $O_3(\mathcal{F}) = 1$ and $O^3(\mathcal{F}) = \mathcal{F}$, and S_2 supports 6 (see Table 1) we obtain 24 fusion systems which are direct products $\mathcal{F}_1 \times \mathcal{F}_2$ of fusion systems on S_1 and S_2 . There are 2 fusion systems \mathcal{F} on S_1 for which $O^{3'}(\mathcal{F})$ has index 2 and 3 such systems on S_2 . Hence there are 6 "diagonal" systems of shape $(O^{3'}(\mathcal{F}_1) \times O^{3'}(\mathcal{F}_2)) : 2$. This accounts for all the systems and we do not list them individually.

A.6.5. **SmallGroup**($3^7, 8707$). This group is $S = S_1 \times S_2$ with $S_1 = 3^{1+2}_+$ a Sylow 3-subgroup of PSL₃(3) and $S_2 = B(3, 4; 0, 1, 0, 0) = B(3, 4; 0, 0, 2, 0)$. As in A.6.4, S_1 supports 4 fusion systems \mathcal{F} of which 2 contain $O^{3'}(\mathcal{F})$ with index 2 and S_2 supports 2 fusion systems, only one of which has this property. From this we construct 10 fusion systems of the form $\mathcal{F}_1 \times \mathcal{F}_2$ and $(O^{3'}(\mathcal{F}_1) \times O^{3'}(\mathcal{F}_2)) : 2$ in which \mathcal{F}_i is a fusion system on S_i . Again they are not individually listed.

A.6.6. **SmallGroup**($3^7, 8709$). This group is $S = S_1 \times S_2$ with $S_1 = 3^{1+2}_+$ and $S_2 = B(3, 4; 0, 0, 0, 0)$. As above there are 4 fusion systems \mathcal{F} on S_1 of which 2 contain $O^{3'}(\mathcal{F})$ with index 2 and 7 fusion systems on S_2 , 3 of which have this property ($\mathcal{F}(3^4, 9, 4)$ is simple). This accounts for all $34 = 4 \cdot 7 + 2 \cdot 3$ fusion systems and we do not list them individually.

A.6.7. **SmallGroup**($3^7, 8713$). This group is isomorphic to a Sylow 3-subgroup S of $P\Gamma L_6(4)$. We let A be the unique elementary abelian subgroup of index 9. We have S is the image in $P\Gamma L_6(4)$ of a Sylow 3-subgroup T of $GL_3(4) \times GL_3(4)$. Now A is the image of the unique subgroup of T which is elementary abelian of order 3^6 and R is the image of 3^{1+2}_+ times the second factor. Notice that R is not normal in the normalizer of T. There is just one fusion system.

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(R)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	$2 \times \text{Sym}(6)$	$2 \times \mathrm{GL}_2(3)$	$2 \times \text{SDih}(16)$	$P\Gamma L_6(4)$

TABLE 28. Saturated fusion systems on a Sylow 3-subgroup of $PGL_6(4)$

A.6.8. **SmallGroup**(3^7 , 9035). This group is isomorphic to a Sylow 3-subgroup of Co₃. It has a unique subgroup A which is elementary abelian of index 9. We infer from the structure of Co₃ that S has a subgroup R of index 3 which is extraspecial. Notice that as $|Z_2(S)| = 3^3$, R is the unique extraspecial subgroup of index 3.

TABLE 29. Saturated fusion systems on a Sylow 3-subgroup of Co_3

\mathcal{F}	$\operatorname{Out}_{\mathcal{F}}(A)$	$\operatorname{Out}_{\mathcal{F}}(R)$	$\operatorname{Out}_{\mathcal{F}}(S)$	Example
1	$2 \times M_{11}$	$4 \circ 2 \cdot \operatorname{Sym}(6)$	$2 \times \text{Dih}(8)$	Co_3

Appendix B. Finding overgroups with a given Sylow *p*-subgroup.

A key part to our algorithm requires that for each proto-essential subgroup E of S we determine all the candidates for $\operatorname{Aut}_{\mathcal{F}}(E)$. To determine these possibilities we have as input $\operatorname{Aut}_{S}(E)$ as a subgroup of $\operatorname{Aut}(E)$ and we know $\operatorname{Aut}_{S}(E)$ should be a Sylow *p*-subgroup of $\operatorname{Aut}_{\mathcal{F}}(E)$. In this short section we present an algorithm which, given a prime *p*, group *G* and *p*-subgroup *T* determines up to *G*-conjugacy all the subgroups of *G* which contain *T* as a Sylow *p*-subgroup.

Suppose that $H \leq G$ and $T \in \operatorname{Syl}_p(H)$. Then by definition $O^{p'}(H) = \langle T^H \rangle$ and $H = N_H(T)O^{p'}(H)$ by the Frattini Argument. We first find the candidates for overgroups H with $H = O^{p'}(H)$. Denote the smallest subnormal subgroup of G which contains T by $\operatorname{sn}(G,T)$. Thus $\operatorname{sn}(G,T)$ is the intersection of all the subnormal subgroups of G which contain T. It can be calculated by setting $G_0 = G$ and, for $i \geq 1$, $G_i = \langle T^{G_{i-1}} \rangle$. Then $G_{\infty} = \operatorname{sn}(G,T)$.

Lemma B.1. Suppose that $H = O^{p'}(H)$ has $T \in Syl_p(H)$. Then $H \leq sn(G,T)$.

Proof. Suppose that K is a subnormal subgroup of G which contains T. Then $H \cap K$ is subnormal in H and contains T. Hence $K \ge O^{p'}(H) = H$. It follows that

$$H \le \bigcap_{\substack{T \le K \\ K \text{ subnormal in } G}} K = \operatorname{sn}(G, T).$$

Our algorithm proceeds as follows. Suppose that $T \leq X$.

- (1) Replace X by $X_{\infty} = \operatorname{sn}(X, T)$ and set $\mathcal{X} = \emptyset$.
- (2) Determine the maximal subgroups M_1, \ldots, M_k of X_{∞} up to X_{∞} -conjugacy.
- (3) For each maximal subgroup M_i , determine up to M_i -conjugacy the subgroups of M_i which are X_{∞} -conjugate to T. Create conjugates M_{ij} of M_i which contain T from these conjugacy classes. For each M_{ij} -conjugacy class add the subnormal closure of T in M_{ij} to \mathcal{X} .
- (4) For each new member $X \in \mathcal{X}$ go to step (2). Continue this until the only new member is T.
- (5) For each element of \mathcal{X} determine whether or not T is a Sylow *p*-subgroup; if it is not, remove it from \mathcal{X} .
- (6) For each $H_0 \in \mathcal{X}$, set $N = N_{N_G(T)}(H_0)$ and determine the subgroups M of N which contain T as a Sylow *p*-subgroup up to N-conjugacy. Make the subgroup H_0M and add it to the list of subgroups with T as a Sylow *p*-subgroup.

We make some remarks concerning the implementation of this algorithm in our programs. By Lemma 4.5, if $\operatorname{Out}_S(E)$ is not cyclic or quaternion then $\operatorname{Out}_{\mathcal{F}}(E)$ is not soluble and the command Subgroups(G:NonSolvable:=true) can be implemented as part of a timely alternative to the algorithm provided above. When $\operatorname{Out}_S(E)$ is cyclic our algorithm is preferable.

APPENDIX C. AN EXAMPLE

Take $G = \mathrm{SL}_4(2)$ and $S \in \mathrm{Syl}_2(G)$. The initial calculation before the calculation of potential Borel groups provides 3 Aut(S)-conjugacy classes of proto-essential subgroups. They have orders 32, 32 and 16. The total number of proto-essential subgroups is 5. The program calculates that there are two potential Borel groups, B = S and B = S : C where C is cyclic of order 3. There is an elementary abelian subgroup E of order 16 which is normal of index 4 in S. It follows that $\mathrm{Out}_S(E) \cong C_2 \times C_2$ and that a candidate for $\mathrm{Aut}_{\mathcal{F}}(E)$ contains a subgroup $\mathrm{SL}_2(4)$. The program recognizes this cannot be an essential subgroup if B = S, rather in this case we find a unique saturated fusion system with 3 essential subgroups isomorphic to $\mathcal{F}_S(\mathrm{Alt}(8))$. When B = S : C, the output is $\mathcal{F}_S(\mathrm{PSU}_4(2))$.
