Abstract *Recently, some studies have constructed one-coordinate arithmetics on elliptic curves. For example, formulas of the x-coordinate of Montgomery curves, x-coordinate of Montgomery$^-$ curves, w-coordinate of Edwards curves, w-coordinate of Huff's curves, ω-coordinates of twisted Jacobi intersections have been proposed. These formulas are useful for isogeny-based cryptography because of their compactness and efficiency.*
In this paper, we define a novel function on elliptic curves called the generalized Montgomery coordinate that has the five coordinates described above as special cases. For a generalized Montgomery coordinate, we construct an explicit formula of scalar multiplication that includes the division polynomial, and both a formula of an image point under an isogeny and that of a coefficient of the codomain curve.
Finally, we present two applications of the theory of a generalized Montgomery coordinate. The first one is the construction of a new efficient formula to compute isogenies on Montgomery curves. This formula is more efficient than the previous one for high degree isogenies as the √élu's formula in our implementation. The second one is the construction of a new generalized Montgomery coordinate for Montgomery$^-$ curves used for CSURF.

Keywords: isogeny-based cryptography, Vélu's formulas, elliptic curves, Kummer line, generalized Montgomery coordinates

2010 Mathematics Subject Classification: 94A60, 14Q05

1 INTRODUCTION

For both mathematics and cryptography, it is an interesting problem for abelian varieties to construct formulas using few coordinates for their group arithmetics. In fact, there have been several studies that have used Kummer varieties to construct such formulas describing arithmetic of abelian varieties in unified coordinates. These theories are classically known to be due to theta functions of level 2. In 1986, D.V. and G.V Chudnovsky constructed some algorithms by using this theory [10]. Montgomery provided a scalar multiplication algorithm via x-coordinates of Montgomery curves [34]. In 2009, Gaudry and Lubicz constructed formulas of group arithmetics of characteristic 2 in [20]. Moreover, Lubicz and Robert proposed compatible group arithmetics of Kummer varieties in [32]. Karati and Sarker investigated the connection between elliptic curves of Legendre form and Kummer lines [27]. In 2018, Hisil and Renes described the relationship of Kummer lines and some popular elliptic curves (Montgomery curves and twisted Edwards curves) [21].

Apart from the above, recently, the development of researches about isogeny-based cryptography has increased interest in efficient and compact isogeny computations of elliptic curves. Indeed, several studies have proposed formulas of scalar multiplications and isogeny computations by using only one-coordinate systems of elliptic curves. For example, formulas via the x-coordinates of Montgomery curves, w-coordinates of Edwards curves, w-coordinates of Huff's curves, and ω-coordinates of twisted Jacobi intersections are known. These constructions have been performed individually. Table 1 summarizes such studies. These one-coordinate formulas are often used in isogeny-based cryptography owing to their compactness and efficiency. Studies have constructed efficient formula for each of the coordinates. Meyer and Reith constructed efficient formulas for isogeny computations of the x-coordinate of Montgomery curves [33], and Bernstein *et al.* developed a method of computing this formula in $\tilde{O}(\sqrt{\ell})$ times [5], while the original Vélu's formulas are computed in $O(\ell)$ times. They described this method on the x-coordinates of Montgomery curves. This method has been extended to the w-coordinate of Edwards curves [35] and the w-coordinate of Huff's curves [41, 28].

The greatness of these coordinates is that they write down both scalar multiplications and isogeny computations in the language of one-coordinate systems. Unfortunately, as mentioned above, these coordinates have been

proposed individually, and there is no framework for handling these coordinates in a unified way as far as we know. As a classical trial to unify some one-coordinate type formulas, we know the theory of Kummer varieties (especially Kummer lines). Even using this theory, it seems hard to unify formulas of the coordinates in the previous paragraph. Indeed, the theory of Kummer lines is a framework for some one-coordinate type formulas of "scalar multiplications"; however, this theory cannot unify formulas of isogeny computations. Certainly, there are some studies about isogeny computations from the theory of Kummer varieties. For example, Lubicz and Robert constructed higher dimensional analogs of Vélu's formulas via theta functions [31], and Cosset and Robert proposed the algorithm to compute (ℓ, ℓ)-isogenies via the theory of theta functions [11]. Unfortunately, these methods of computing isogenies seem not suitable to unify the target formulas, because these methods focus on higher degree abelian varieties and are too complex. Moreover, Costello proposed an algorithm to compute Richelot isogenies of Kummer surfaces of Jacobian varieties of genus-2 curves [12]. This study excels at computing Richelot isogenies; however, it is hard to adapt the method to unify formulas of isogeny computations on curves because this study considers special cases of isogenies. Therefore, we propose the following question:

Can we construct one-coordinate formulas of scalar multiplication and isogeny computation of elliptic curves for isogeny-based cryptography in a unified manner like the theory of Kummer lines?

From the theory of divisors of functions, we can define a generalized coordinate of elliptic curves, and construct explicit one-coordinate type formulas to compute scalar multiplications and isogeny computations. Unfortunately, the use of divisors instead of theta functions makes it difficult to extend the theory to higher dimensional abelian varieties. On the other hand, as far as we focus on the computational aspects of elliptic curves, the construction from divisors is more natural than that from theta functions.

1.1 CONTRIBUTION

In this paper, we provide an affirmative answer to the above research question. We contribute to the literature by improving the visibility of the isogeny computation of different forms of elliptic curves (see Figure 1). The followings are specific contributions of the paper.

Defining a generalized Montgomery coordinate

The core of our research is the introduction of a novel function on elliptic curves, which we call a generalized Montgomery coordinate (Definition 1). This is a generalization of coordinates that can be used to construct one-coordinate formulas on elliptic curves, *e.g.*, the x-coordinates of Montgomery curves, x-coordinates of Montgomery$^-$ curves, w-coordinates of Edwards curves, w-coordinates of Huff's curves, and ω-coordinates of twisted Jacobi intersections. Because these coordinates have similar divisors, we can obtain a generalization of them by considering divisors with the appropriate form. In particular, the set of poles and zero points of these coordinates can be considered a finite subgroup $\mathcal{G}$ of the elliptic curve E and the shifted set of $\mathcal{G}$ by one point in E, respectively. More precisely, a generalized Montgomery coordinate for an elliptic curve E can be defined by specifying a finite subgroup $\mathcal{G} \subset E$ as poles and the set $\mathcal{R}_0 = R_0 + \mathcal{G}$ as zero points, where R_0 is a point such that $2R_0 \in \mathcal{G}$ and $R_0 \notin \mathcal{G}$. Indeed, we can demonstrate that a generalized Montgomery coordinate is essentially the same as the composition of an isogeny and the x-coordinate of a (standard) Montgomery curve (Theorem 2).

Constructing explicit formulas

Moreover, we construct explicit formulas for scalar multiplications and isogeny computations via a generalized Montgomery coordinate. Two formulas are used to construct a formula for scalar multiplication: one is for differential addition, and the other is for doubling. We construct both formulas by considering the divisors of the functions of the computational results of each formula. For example, the doubling formula is constructed from the divisor of the function $h \circ [2]$, where h is a generalized Montgomery coordinate. This method of construction has a high affinity with the definition of a generalized Montgomery coordinate. Furthermore, two formulas are used to construct

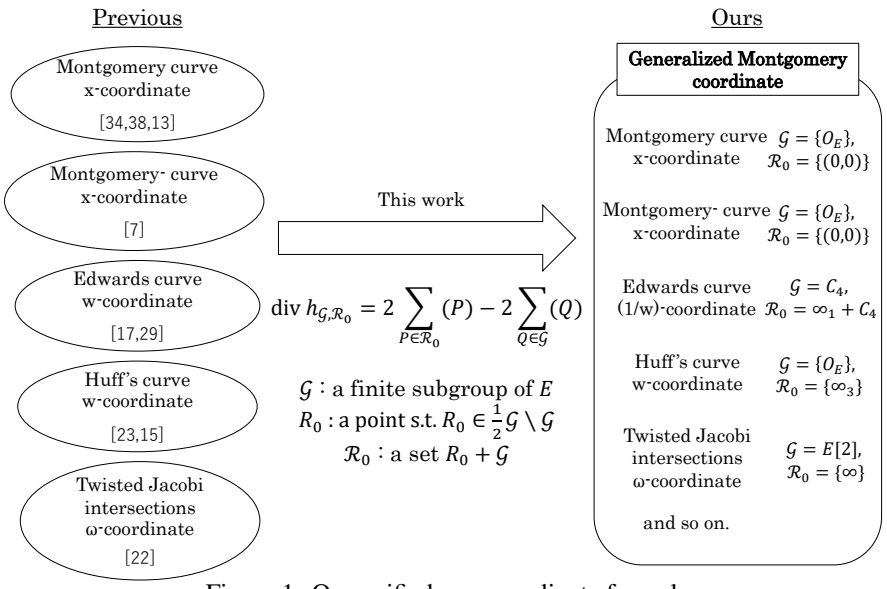

Figure 1: Our unified one-coordinate formulas

the formula of isogeny computation: one is for computing an image point under an isogeny, and the other is for computing a coefficient of the codomain curve under an isogeny. We construct the first formula in the same manner as the formula of scalar multiplication. However, the second formula cannot be constructed using divisors because it is not a function over an elliptic curve. We construct the second formula using the 2-torsion method provided in [13].

Analyzing the difference between multiple formulas

As mentioned earlier, the formula to compute a coefficient of a codomain curve under an isogeny is not constructed using its divisor. Therefore, this formula has several representations. We know that the formula of Montgomery curves proposed in [38] and that proposed in [33] are different. We analyze these differences to describe all formulas using generalized Montgomery coordinates, and we prove that this difference is due to the division polynomial of the generalized Montgomery coordinates (Theorem 10).

Applications

We believe that the theory of a generalized Montgomery coordinate has many applications. In this paper, we consider two applications as an initial trial. First, we construct a new efficient formula to compute isogenies on Montgomery curves. This formula is obtained by transplanting the formula of Edwards curves to Montgomery curves, and it is more efficient than the previous formula for high degree isogenies in our implementation. Next, we propose a new generalized Montgomery coordinate of Montgomery$^-$ curves called the w-coordinate. We can construct a new CSURF algorithm [7] via the w-coordinate. Some accelerating techniques have been used in previous algorithms of CSURF, and we must consider a proper isogeny from a Montgomery$^-$ curve to a Montgomery curve to use these techniques. However, our proposed algorithm can use these techniques through the w-coordinate without considering any isogenies. Thus, our new algorithm provides a simple implementation of CSURF.

1.2 ORGANIZATION.

In Section 2, we introduce some mathematical concepts as preliminaries. In Section 3.1, we define the generalized Montgomery coordinate and basic notations related to it, and in Section 3.2, we prove some important properties of a generalized Montgomery coordinate. Section 3.3 provides some examples of a generalized Montgomery coordinate. We prove theorems of formulas of differential addition and doubling in Section 4.1, and we define division polynomials of the generalized Montgomery coordinates in Section 4.2. In Section 5, we construct formulas to compute isogenies via a generalized Montgomery coordinate. Section 6 shows some applications of the theory of a generalized Montgomery coordinate. Finally, we conclude this paper in Section 7.

2 PRELIMINARIES

In this section, we introduce some important mathematical concepts for our study. The details of the following facts are provided in [39, 19].

Let K be a field. An *elliptic curve defined over* K is a pair (E, O_E) of a smooth algebraic curve E defined over K with genus 1 and a point O_E in $E(K)$. It is known that $E(L)$ has a group structure whose identity element is O_E, where L is an algebraic extension field of K. In this paper, we often use a genus-1 curve E for representing an elliptic curve (omit the identity point O_E), we fix K, and if not mentioned, we always fix E over $\overline{K}$ (*i.e.,* it is defined over the algebraic closure of K). A *Montgomery curve* is an elliptic curve defined by the equation $y^2 = x^3 + \alpha x^2 + x$ ($\alpha \neq \pm 2$). The identity point of a Montgomery curve is a point at infinity. We call a coefficient α a *Montgomery coefficient*.

Let n be an integer. We denote the multiplication-by-n map between elliptic curves by $[n]$, and denote a point $[n](P)$ by nP. We define the *n-torsion subgroup of* $E(\overline{K})$ as $E[n] = \{P \in E(\overline{K}) \mid nP = O_E\}$. If $\mathrm{ch}(K) = 0$ or $\mathrm{ch}(K) \nmid n$, then it holds that $E[n] \cong \mathbb{Z}/n\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$. Here, $\mathrm{ch}(K)$ is the characteristic of K. For a subset $S \subset E$, we define the set $\frac{1}{2}S$ as $\frac{1}{2}S := \{P \in E \mid 2P \in S\}$.

Let E and E' be elliptic curves defined over K. An *isogeny* $\phi\colon E \to E'$ *defined over* K is a nontrivial morphism defined over K of algebraic curves such that $\phi(O_E) = O_{E'}$. It is known that ϕ is a group morphism of elliptic curves. From an isogeny ϕ, we obtain an injective map $\phi^*\colon \overline{K}(E') \to \overline{K}(E)$, where $\overline{K}(E)$ and $\overline{K}(E')$ are the function fields of E and E' respectively. The *degree of* ϕ denoted by $\deg\phi$ is the degree of the finite extension $\overline{K}(E)/\phi^*(\overline{K}(E'))$. If this extension is separable, then an isogeny ϕ is called a *separable isogeny*. If an isogeny ϕ is separable, it holds that $\deg\phi = \#\ker\phi$. An *ℓ-isogeny* is a separable isogeny whose kernel is a cyclic subgroup of order ℓ. For any isogeny $\phi : E \to E'$, there is an isogeny $\hat{\phi} : E' \to E$ such that $\phi \circ \hat{\phi} = [\deg\phi]\colon E' \to E'$ and $\hat{\phi} \circ \phi = [\deg\phi]\colon E \to E$. This isogeny is called the *dual isogeny of* ϕ. Let G be a finite subgroup of E. There is a unique elliptic curve E/G up to isomorphism and a separable isogeny $\phi\colon E \to E/G$ such that $\ker\phi = G$. Vélu proposed formulas to compute this isogeny in [40]. We call these *Vélu's formulas*.

Let $P \in E$. Let ord_P be the normalized valuation on the local ring of E at P. The *divisor group of an elliptic curve* E is the free commutative group generated by points of E, and a *divisor* is an element of the divisor group of E. Let f be a function in $\overline{K}(E)^\times$. The *divisor of* f, denoted by $\mathrm{div}\, f$, is defined as follows:

$$\mathrm{div}\, f = \sum_{P \in E} \mathrm{ord}_P\,(f)(P).$$

Let $D = \sum n_P(P)$ be a divisor. There is a function $f \in \overline{K}(E)$ such that $D = \mathrm{div}\, f$ if and only if $\sum n_P = 0$ and $\sum n_P P = O_E$ in E. Let $g \in \overline{K}(E)^\times$. It holds that $\mathrm{div}\, f = \mathrm{div}\, g$ if and only if there is a constant value $c \in \overline{K}^\times$ such that $f = c \cdot g$.

3 GENERALIZED MONTGOMERY COORDINATES AND THEIR BASIC PROPERTIES

In this section, we define a new function on elliptic curves called the generalized Montgomery coordinate. This function gives formulas to compute isogenies, which are independent of the forms of elliptic curves.

In this paper, we always let K be a field whose characteristic is not 2. It is not a problem for isogeny-based cryptography, because fields with large characteristic are always used in it so far.

3.1 DEFINITION OF A GENERALIZED MONTGOMERY COORDINATE

In this subsection, we define a generalized Montgomery coordinate.

Before defining a generalized Montgomery coordinate, we consider properties common to the x-coordinate of Montgomery curves, the x-coordinate of Montgomery$^-$ curves, the w-coordinate of Edwards curves, and the w-coordinate of Huff's curves. These curves have several common properties. Particularly, we think that the following four properties are important as coordinates used in computations. Here, we denote a coordinate on an elliptic curve E as h.

i) It holds that $h \in \overline{K}(E)$.

ii) There is a finite subgroup $\mathcal{G} \subset E$ such that

$$h(P) = h(Q) \iff P + Q \in \mathcal{G} \text{ or } P - Q \in \mathcal{G}.$$

iii) It holds that O_E is a pole of h.

iv) There is a point R_0 satisfying $2R_0 \in \mathcal{G}$ and $h(R_0) = 0$.

The property (i) indicates that h is a morphism between E and the projective line $\mathbb{P}^1$. The property (ii) claims that $h(P) = h(Q)$ if and only if the addition of P and Q or their difference belongs to a finite subgroup $\mathcal{G}$. This property comes from the intuition that coordinates with good symmetry may be related to a subgroup of elliptic

Table 2: Examples of normalized generalized Montgomery coordinates (Definition 1)

Forms	Coordinate	$h_{\mathcal{G},\mathcal{R}_0}$ (normalized)	$\mathcal{G}$	$\mathcal{R}_0$
Montgomery	x	x	$\{O_E\}$	$\{(0,0)\}$
Montgomery$^-$	x	$\sqrt{-1}x$	$\{O_E\}$	$\{(0,0)\}$
Edwards	$w = dx^2y^2$	w^{-1}	C_4	$\infty_1 + C_4$
Huff	$w = 1/(xy)$	w	$\{O_E\}$	$\{\infty_3\}$
Twisted Jacobi intersections	$\omega = \sqrt{ab}x^2$	ω^{-1}	$E[2]$	{points at infinity}

curves. This intuition is also found in other papers. For example, Kohel constructed an efficient model of elliptic curves in characteristic 2 based on this intuition [30]. The property (iii) means $h(O_E) = \infty = (1:0) \in \mathbb{P}^1$, and the property (iv) means there is a zero point of h whose doubling belongs to $\mathcal{G}$.

From the properties (ii-iv), we obtain zero points and poles of h. Therefore, we can write down the condition of the divisor of h. By considering the simplest condition of $\operatorname{div} h$, we can construct the following definition of a generalized Montgomery coordinate.

Definition 1 (Generalized Montgomery coordinate)**.** *Let E be an elliptic curve defined over $\overline{K}$. Let $\mathcal{G}$ be a finite subgroup of E, and let R_0 be a point satisfying $R_0 \notin \mathcal{G}$ and $2R_0 \in \mathcal{G}$. We denote the set $R_0 + \mathcal{G}$ by $\mathcal{R}_0$. If a function $h_{\mathcal{G},\mathcal{R}_0} \in \overline{K}(E)$ satisfies the following equality, we call $h_{\mathcal{G},\mathcal{R}_0}$ the generalized Montgomery coordinate of E with respect to $\mathcal{G}$ and $\mathcal{R}_0$:*

$$\operatorname{div} h_{\mathcal{G},\mathcal{R}_0} = 2\sum_{P\in\mathcal{G}}(P + R_0) - 2\sum_{P\in\mathcal{G}}(P).$$

Here, $P + R_0$ means a point addition of P and R_0 in E.

Remark 1. *When we fix $\mathcal{G}$ and $\mathcal{R}_0$, a generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$ always exists, because it holds that*

$$2\sum_{P\in\mathcal{G}} P + (2\#\mathcal{G})R_0 - 2\sum_{P\in\mathcal{G}} P = O_E.$$

Remark 2. *Let ϑ_0 and ϑ_1 be functions of $\mathbb{C}\times\mathcal{H}$ defined by*

$$\vartheta_0(z,\tau) = \sum_{n=-\infty}^{\infty} e^{\pi i n^2\tau + 2\pi i n z}, \quad \vartheta_1(z,\tau) = \sum_{n=-\infty}^{\infty} e^{\pi i n^2\tau + 2\pi i n z + \pi i n},$$

where $\mathcal{H}$ is the upper half-plane. Let Λ_τ be a $\mathbb{Z}$-lattice generated by 1 and τ, and E_τ an elliptic curve over $\mathbb{C}$ biholomorphic to $\mathbb{C}/\Lambda_\tau$. Now, we fix τ. In the theory of Kummer lines, we use a composition of a function $\vartheta_0^2/\vartheta_1^2$ and an automorphism of $\mathbb{P}^1$ as a unify coordinate. Because $\vartheta_0^2/\vartheta_1^2$ is well-defined over $\mathbb{C}/\Lambda$, we consider this function as a coordinate of E_τ. It is easy to see that the divisor of a function $\vartheta_0^2/(\vartheta_0^2(0)\vartheta_1^2 - \vartheta_1^2(0)\vartheta_0^2)$ is $2(R) - 2(O_{E_\tau})$, where R is a point of order 2 in E_τ. Therefore, as far as we concentrate on elliptic curves, a generalized Montgomery coordinate is a generalization of a coordinate from theta functions.

Remark 3. *The name "generalized Montgomery coordinate" comes from Theorem 2.*

Let E be a Montgomery curve, let $\mathcal{G} = \{O_E\}$, and let $\mathcal{R}_0 = \{(0,0)\}$; then, the x-coordinate of E is a normalized generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$. As shown in Table 2, other coordinates are also obtained by determining $\mathcal{G}$ and $\mathcal{R}_0$ properly. The definition of a normalized generalized Montgomery coordinate is given in Definition 3. In subsection 3.3, we show that these coordinates are generalized Montgomery coordinates.

Next, we introduce an important notation regarding a generalized Montgomery coordinate which plays a role as a standard Montgomery coefficient. Before defining this notation, we prove the following lemma.

Lemma 1. *Let E be an elliptic curve, and let $\mathcal{G}$ be a finite subgroup of E. Then, the set $\frac{1}{2}\mathcal{G}$ is a subgroup of E including $\mathcal{G}$ and is decomposed as follows:*

$$\frac{1}{2}\mathcal{G} = \mathcal{G} \sqcup (R_0 + \mathcal{G}) \sqcup (R_1 + \mathcal{G}) \sqcup (R_0 + R_1 + \mathcal{G}),$$

where R_0 is a point in $\frac{1}{2}\mathcal{G} \setminus \mathcal{G}$, and R_1 is a point in $\frac{1}{2}\mathcal{G} \setminus (\mathcal{G} \sqcup (R_0 + \mathcal{G}))$.

We denote $R_1 + \mathcal{G}$ by $\mathcal{R}_1$.

Proof. Let $[2]$ be a doubling map. Since $[2]^{-1}(\mathcal{G}) = \frac{1}{2}\mathcal{G}$, $\frac{1}{2}\mathcal{G}$ is a subgroup of E. Note that $[2]|_{\frac{1}{2}\mathcal{G}} \colon \frac{1}{2}\mathcal{G} \to \mathcal{G}$ is surjective. As the kernel of $[2]|_{\frac{1}{2}\mathcal{G}}$ is $E[2]$, the index of $\mathcal{G}$ in $\frac{1}{2}\mathcal{G}$ is 4. Since $[2](\frac{1}{2}\mathcal{G}) \subset \mathcal{G}$, it holds that

$$\left(\frac{1}{2}\mathcal{G}\right)/\mathcal{G} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}.$$

This completes the proof of Lemma 1. □

Now, we define a generalized Montgomery coefficient.

Definition 2 (Generalized Montgomery coefficient)**.** *Let $(E, h_{\mathcal{G}_E,\mathcal{R}_0})$ be a pair of an elliptic curve defined over K and its normalized generalized Montgomery coordinate. Let $\mathcal{R}_1$ be the set defined in Lemma 1, and let R_1 be a point in $\mathcal{R}_1$. We call a value $\alpha_{h_{\mathcal{G},\mathcal{R}_0}} \in \overline{K}$ defined by*

$$\alpha_{h_{\mathcal{G},\mathcal{R}_0}} = -h_{\mathcal{G},\mathcal{R}_0}(R_1) - \frac{1}{h_{\mathcal{G},\mathcal{R}_0}(R_1)}$$

the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$.

Remark 4. *We can easily show that $\alpha_{h_{\mathcal{G},\mathcal{R}_0}}$ is uniquely determined regardless of the way to decide $\mathcal{R}_1$ and R_1 from Theorem 1 and Lemma 2.*

Remark 5. *If $h_{\mathcal{G}_E,\mathcal{R}_0}$ is the x-coordinate of a Montgomery curve, then the generalized Montgomery coefficient is the standard Montgomery coefficient.*

Remark 6. *Let E be an elliptic curve, and let h be a generalized Montgomery coordinate with respect to a finite subgroup $\mathcal{G} \subset E$. Though a Montgomery curve can be determined from its standard Montgomery coefficient, it is not always possible to determine E from the generalized Montgomery coefficient of h and the group structure of $\mathcal{G}$.*

As shown in the following lemma, there is a constant ambiguity in a generalized Montgomery coordinate. For the sake of brevity in future discussions, we define a "normalized" generalized Montgomery coordinate.

Lemma 2. *For the generalized Montgomery coordinate $h_{\mathcal{G},\mathcal{R}_0}$, there exists a constant value c in $\overline{K}^\times$ such that*

$$h_{\mathcal{G},\mathcal{R}_0}(P + R_0) = \frac{c}{h_{\mathcal{G},\mathcal{R}_0}(P)}$$

for any P in E and R_0 in $\mathcal{R}_0$.

Proof. We define the two maps ϕ_1 and ϕ_2 mapping from E to $\mathbb{P}^1$ as

$$\phi_1(z) = h_{\mathcal{G},\mathcal{R}_0}(z + R_0), \quad \phi_2(z) = \frac{1}{h_{\mathcal{G},\mathcal{R}_0}(z)}.$$

By considering zero points and poles of ϕ_1 and ϕ_2 from these definitions (Definition 3.1), we have $\operatorname{div}\phi_1 = \operatorname{div}\phi_2$. Therefore, there is a constant value $c \neq 0$ such that $\phi_1 = c \cdot \phi_2$. □

Definition 3 (Normalized generalized Montgomery coordinate)**.** *If $c = 1$ in Lemma 2, we call $h_{\mathcal{G},\mathcal{R}_0}$ the normalized generalized Montgomery coordinate.*

By replacing $h_{\mathcal{G},\mathcal{R}_0}$ with $\frac{1}{\sqrt{c}}h_{\mathcal{G},\mathcal{R}_0}$, we can always take $h_{\mathcal{G},\mathcal{R}_0}$ as normalized.

3.2 BASIC PROPERTIES OF A GENERALIZED MONTGOMERY COORDINATE

In this subsection, we see some basic properties of a generalized Montgomery coordinate. Theorem 1 shows that a generalized Montgomery coordinate satisfies property ii) in Section 3.1, and Theorem 2 tells us that a normalized generalized Montgomery coordinate is a composition of the x-coordinate of a Montgomery curve and an isogeny.

Theorem 1. *Let $\mathcal{G}$ be a finite subgroup of E, let R_0 be a point such that $2R_0 \in \mathcal{G}$ and $R_0 \notin \mathcal{G}$, and let $\mathcal{R}_0$ be the set $R_0 + \mathcal{G}$. Let $h_{\mathcal{G},\mathcal{R}_0}$ be a generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$. Then, for $P, Q \in E$, it holds that*

$$h_{\mathcal{G},\mathcal{R}_0}(P) = h_{\mathcal{G},\mathcal{R}_0}(Q) \iff P + Q \in \mathcal{G} \text{ or } P - Q \in \mathcal{G}.$$

Proof. First, we prove that the left-hand side follows from the right-hand side. We show

$$h_{\mathcal{G},\mathcal{R}_0}(P) = h_{\mathcal{G},\mathcal{R}_0}(-P+S),$$

for all $S \in \mathcal{G}$ and $P \in E$. For $S \in \mathcal{G}$, we define a map $\phi_S \in \overline{K}(E)$ as follows:

$$\phi_S(z) = h_{\mathcal{G},\mathcal{R}_0}(-z+S).$$

It is clear that $\operatorname{div} h_{\mathcal{G},\mathcal{R}_0} = \operatorname{div} \phi_S$. We now prove that the constant function $h_{\mathcal{G},\mathcal{R}_0}/\phi_S$ is 1 in two cases. If there is a point $\tilde{S}$ such that $2\tilde{S} = S$, $\tilde{S} \notin \mathcal{G}$, and $\tilde{S} \notin \mathcal{R}_0$, we have $h_{\mathcal{G},\mathcal{R}_0}(\tilde{S}) = \phi_S(\tilde{S})$. Because $h_{\mathcal{G},\mathcal{R}_0}(\tilde{S})$ is neither 0 nor ∞, it holds that $h_{\mathcal{G},\mathcal{R}_0} = \phi_S$. Suppose that there is no point satisfying the above property. Take a point $\tilde{S}$ as a point satisfying $2\tilde{S} = S$. Note that $\tilde{S} \in \mathcal{G}$ or $\tilde{S} \in \mathcal{R}_0$. Let R be a point of order 2, and define a function $f \in \overline{K}(E)$ satisfying

$$\operatorname{div} f = \begin{cases} 2(\tilde{S}+R) - 2(\tilde{S}) & (\text{if } \tilde{S} \in \mathcal{G}), \\ 2(\tilde{S}) - 2(\tilde{S}+R) & (\text{if } \tilde{S} \in \mathcal{R}_0). \end{cases}$$

Let R' be a point in $E[2] \setminus \{O_E, R\}$. Because we have

$$f(\tilde{S}+R') = f(-(\tilde{S}+R')+S) \neq 0, \infty,$$

it holds that $f(z) = f(-z+S)$ from considering their divisors. It holds that $(h_{\mathcal{G},\mathcal{R}_0}/f)(z) = c \cdot (h_{\mathcal{G},\mathcal{R}_0}/f)(-z+S)$, where c is a constant value. Since

$$(h_{\mathcal{G},\mathcal{R}_0}/f)(\tilde{S}) = (h_{\mathcal{G},\mathcal{R}_0}/f)(-\tilde{S}+S) \neq 0, \infty,$$

it holds that $c = 1$. Therefore, $h_{\mathcal{G},\mathcal{R}_0}(z) = h_{\mathcal{G},\mathcal{R}_0}(-z+S)$. Note that $h_{\mathcal{G},\mathcal{R}_0}(z) = h_{\mathcal{G},\mathcal{R}_0}(-z)$ by substituting $S = O_E$. We have

$$h_{\mathcal{G},\mathcal{R}_0}(P) = h_{\mathcal{G},\mathcal{R}_0}(Q) \Longleftarrow P+Q \in \mathcal{G} \text{ or } P-Q \in \mathcal{G}.$$

Next, we prove the converse. If $P \in \mathcal{G}$ or $P \in \mathcal{R}_0$, the converse is true. Suppose that $P \notin \frac{1}{2}\mathcal{G}$. Then, we have

$$\#\{Q \in E \mid P+Q \in \mathcal{G} \text{ or } P-Q \in \mathcal{G}\} = 2\#\mathcal{G}.$$

Because $\deg h_{\mathcal{G},\mathcal{R}_0} = 2\#\mathcal{G}$, the converse holds. Suppose that $P \in \mathcal{R}_1 \cup (\mathcal{R}_0 + \mathcal{R}_1)$, where $\mathcal{R}_1$ is the set defined in Lemma 1. From Lemma 1 and the above discussion, if $Q \notin \mathcal{R}_1 \cup (\mathcal{R}_0 + \mathcal{R}_1)$, then it holds that $h_{\mathcal{G},\mathcal{R}_0}(P) \neq h_{\mathcal{G},\mathcal{R}_0}(Q)$. Therefore, it suffices to show that $h_{\mathcal{G},\mathcal{R}_0}(P) \neq h_{\mathcal{G},\mathcal{R}_0}(P+R_0)$. We define a map $\psi \in \overline{K}(E)$ as $\psi(z) = h_{\mathcal{G},\mathcal{R}_0}(z) - h_{\mathcal{G},\mathcal{R}_0}(z+R_0)$. Let $\tilde{R}_0$ be a point such that $2\tilde{R}_0 = R_0$. By considering poles of ψ, we have $\deg \psi = 4\#\mathcal{G}$. Note that points belonging to $\tilde{R}_0 + \mathcal{G}$, $-\tilde{R}_0 + \mathcal{G}$, $\tilde{R}_0 + \mathcal{R}_1$, or $-\tilde{R}_0 + \mathcal{R}_1$ are zero points of ψ. From Lemma 1, these sets are disjoint. Therefore, there are no zero points other than those belonging to these sets. Because $P \pm \tilde{R}_0 \notin \mathcal{G}$ and $P \pm \tilde{R}_0 \notin \mathcal{R}_1$, we have P does not belong to the set of zero points of ψ. Hence, it holds that $\psi(P) \neq 0$. This completes the proof of Theorem 1. □

Next, we state the important theorem (Theorem 2). This theorem shows that a generalized Montgomery coordinate can be seen as a natural generalization of x-coordinates of Montgomery curves.

Theorem 2. *Let $\mathcal{G}$ be a finite subgroup of E with $\operatorname{ch}(K) \nmid \#\mathcal{G}$, let R_0 be a point satisfying $R_0 \in \frac{1}{2}\mathcal{G} \setminus \mathcal{G}$, let $\mathcal{R}_0$ be the set $R_0 + \mathcal{G}$, and let $h_{\mathcal{G},\mathcal{R}_0}$ be a normalized generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$. Then, there is a Montgomery curve E' and a separable isogeny $\phi\colon E \to E'$ with $\ker \phi = \mathcal{G}$ such that $h_{\mathcal{G},\mathcal{R}_0} = x \circ \phi$, where x is the x-coordinate of E'. Moreover, the Montgomery coefficient of E' is the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$.*

Before proving this theorem, we prove the following lemma.

Lemma 3. *If a point $\tilde{R}$ satisfies $h_{\mathcal{G},\mathcal{R}_0}(2\tilde{R}) = 0$, then $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R})^2 = 1$.*

Proof. Because $h_{\mathcal{G},\mathcal{R}_0}(2\tilde{R}) = 0$, we have $2\tilde{R} \in \mathcal{R}_0$. Thus, $4\tilde{R}$ belongs to $\mathcal{G}$. From Lemma 2,

$$h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}+R_0) = \frac{1}{h_{\mathcal{G},\mathcal{R}_0}(\tilde{R})},$$

where $R_0 \in \mathcal{R}_0$. Therefore, by Theorem 1,

$$\frac{1}{h_{\mathcal{G},\mathcal{R}_0}(\tilde{R})} = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}+R_0) = h_{\mathcal{G},\mathcal{R}_0}(3\tilde{R}) = h_{\mathcal{G},\mathcal{R}_0}(-\tilde{R}) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}).$$

This completes the proof of Lemma 3. □

Now, we prove Theorem 2.

Proof of Theorem 2. Let ϕ be a separable isogeny $\phi\colon E \to E/\mathcal{G}$ with $\ker\phi = \mathcal{G}$. Let $\tilde{R}_0$ be a point in E such that $h_{\mathcal{G},\mathcal{R}_0}(2\tilde{R}_0) = 0$. It is easy to see that there is an isomorphism between $E/\mathcal{G}$ and a Montgomery curve E' mapping $2\phi(\tilde{R}_0)$ to $(0,0)$. If necessary, we compose this isomorphism and the map $E' \to E''$; $(x,y) \mapsto (-x, \sqrt{-1}y)$, and we denote E'' by E'. Then, the x-coordinate of $\phi(\tilde{R}_0)$ in E' is $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0)$, because $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0) = \pm 1$ from Lemma 3. It is easy to check that

$$\operatorname{div} h_{\mathcal{G},\mathcal{R}_0} = \operatorname{div}(x \circ \phi).$$

Therefore, $h_{\mathcal{G},\mathcal{R}_0} = x \circ \phi$.

Let R_1 be a point of E defined in Lemma 1. Then, the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$ is $-h_{\mathcal{G},\mathcal{R}_0}(R_1) - \frac{1}{h_{\mathcal{G},\mathcal{R}_0}(R_1)}$. In contrast, $\phi(R_1)$ is a point of order 2 in E' other than $(0,0)$. Therefore, the Montgomery coefficient of E' can be represented by $-x(\phi(R_1)) - \frac{1}{x(\phi(R_1))}$. From $h_{\mathcal{G},\mathcal{R}_0} = x \circ \phi$, this completes the proof of Theorem 2. □

Although we can define a normalized generalized Montgomery coordinate as the composition of an isogeny and the x-coordinate of a Montgomery curve from Theorem 2, we adopt Definition 1 (*i.e.,* the definition from its divisor). The main reason to define generalized Montgomery coordinates in this way is that this definition does not need to consider explicit forms of elliptic curves. This means that our definition seems to be more essential than that from a Montgomery curve. In fact, by the similar proof of Theorem 2, we can also prove naturally that a normalized generalized Montgomery coordinate is the composition of an isogeny and the w-coordinate of a Huff's curve. That is to say, it is not crucial to describe a generalized Montgomery coordinate via a Montgomery curve. Moreover, if we consider an extension of a generalized Montgomery coordinate in the future, Definition 1 looks more suitable than the definition from a Montgomery curve. It is because divisors are basic concepts for algebraic varieties, and have a wide scope of application. For the same reason as above, though it is trivial that the formula of scalar multiplication and the formula of isogeny computation via a generalized Montgomery coordinate immediately hold from Theorem 2 and the formulas on the x-coordinate of Montgomery curves, we prove these formulas from the theory of divisors without using formulas on Montgomery curves.

3.3 EXAMPLES OF GENERALIZED MONTGOMERY COORDINATES

In this subsection, we show some examples of generalized Montgomery coordinates already used for computations of isogenies. Table 2 is the summary of this subsection.

3.3.1 MONTGOMERY CURVES.

Montgomery curves are elliptic curves named after Montgomery [34] defined by the equation $y^2 = x^3 + \alpha x^2 + x$, where $\alpha \neq \pm 2$. It is known that some computations of Montgomery curves are realized using x-coordinates [6, 13]. Note that the pole of a x-coordinate is a point at infinity, that is O_E. One can see that the x-coordinate of Montgomery curves is a generalized Montgomery coordinate with respect to $\{O_E\}$ and $\mathcal{R}_0 = \{(0,0)\}$. In fact, it holds that

$$\operatorname{div} x = 2((0,0)) - 2(O_E).$$

Moreover, direct calculations lead to the fact that $x(P + (0,0)) = 1/x(P)$. Therefore, x-coordinates are normalized.

3.3.2 MONTGOMERY$^-$ CURVES.

Montgomery$^-$ curves are defined by the equation
$y^2 = x^3 + \alpha x^2 - x$, where $\alpha \neq \pm 2\sqrt{-1}$. From [7], it holds that some computations of Montgomery$^-$ curves are computed only using x-coordinates. Since it holds that

$$\operatorname{div} x = 2((0,0)) - 2(O_E),$$

we have that the x-coordinate of Montgomery$^-$ curves is a generalized Montgomery coordinate with respect to $\{O_E\}$ and $\mathcal{R}_0 = \{(0,0)\}$. Moreover, direct calculations lead to the fact that $x(P + (0,0)) = -1/x(P)$. Therefore, $\sqrt{-1}x$ is a normalized generalized Montgomery coordinate.

Remark 7. *Formulas of Montgomery$^-$ curves shown in [7] are obtained by applying formulas of a normalized generalized Montgomery coordinate, which we will prove in Section 4, to* $\sqrt{-1}x$.

3.3.3 EDWARDS CURVES.

Edwards curves are elliptic curves defined by the equation $x^2 + y^2 = 1 + dx^2y^2$, where $d \neq 0, 1$ [16, 3]. Note that the projective model of an Edwards curve is $X^2 + Y^2 = Z^2 + dT^2,\ XY = ZT$. The w-coordinates of Edwards curves are defined as $w = dx^2y^2$. It is known that there are some formulas on the w-coordinate of Edwards curves [17, 29]. For an Edwards curve E, we denote a cyclic group $\{(0, \pm 1), (\pm 1, 0)\}$ in $E(\overline{K})$ by C_4. Because

$$\begin{aligned}\operatorname{div} x &= ((0,1)) + ((0,-1)) - (\infty_1) - (\infty_2),\\ \operatorname{div} y &= ((1,0)) + ((-1,0)) - (\infty_3) - (\infty_4),\end{aligned}$$

it holds that

$$\operatorname{div} w = 2\sum_{P \in C_4}(P) - 2\sum_{P \in C_4}(P + \infty_1),$$

where ∞_1 and ∞_2 are points at infinity of order 2, and ∞_3 and ∞_4 are points at infinity of order 4. Therefore, w^{-1} is a generalized Montgomery coordinate with respect to C_4 and $\mathcal{R}_0 = \infty_1 + C_4$. From direct calculations, we have $w(P + \infty_1) = 1/w(P)$. Hence, w^{-1} is a normalized generalized Montgomery coordinate.

Moreover, there are some well-known formulas using the y-coordinates of Edwards curves. In fact, [9] shows formulas for scalar multiplications and isogeny computations via y-coordinates of Edwards curves. It is easy to check that the y-coordinate is not a generalized Montgomery coordinate; however, from the following three equations:

$$\begin{aligned}\operatorname{div}(1-y) &= 2((0,1)) - (\infty_3) - (\infty_4),\\ \operatorname{div}(1+y) &= 2((0,-1)) - (\infty_3) - (\infty_4),\\ y(P + (0,-1)) &= -y(P),\end{aligned}$$

it holds that a function $(1 + y)/(1 - y)$ is a normalized generalized Montgomery coordinate. Therefore, formulas of y-coordinates of Edwards curves are obtained by formulas of generalized Montgomery curves.

Remark 8. *The above discussions about Edwards curves can be adapted to twisted Edwards curves proposed in [4] defined by the following equation:*

$$ax^2 + y^2 = 1 + dx^2y^2.$$

It is because this curve is isomorphic to an Edwards curve $x^2 + y^2 = 1 + (d/a)x^2y^2$.

3.3.4 HUFF'S CURVES.

Huff's curves are defined by the equation
$cx(y^2 - 1) = y(x^2 - 1)$, where $c \neq \pm 1$ [24, 26]. It is known that some formulas of Huff curves can be computed using w-coordinates defined as $w = 1/(xy)$ [15, 23]. Since

$$\begin{aligned}\operatorname{div} x &= (O_E) + (\infty_1) - (\infty_2) - (\infty_3),\\ \operatorname{div} y &= (O_E) + (\infty_2) - (\infty_1) - (\infty_3),\end{aligned}$$

it holds that

$$\operatorname{div} w = 2(\infty_3) - 2(O_E),$$

where ∞_1, ∞_2, and ∞_3 are points at infinity of order 2. Therefore, w is a generalized Montgomery coordinate with respect to $\{O_E\}$ and $\mathcal{R}_0 = \{\infty_3\}$. From direct calculations, we have $w(P + \infty_3) = 1/w(P)$. Therefore, w is a normalized generalized Montgomery coordinate.

3.3.5 TWISTED JACOBI INTERSECTIONS.

Twisted Jacobi intersections are defined by the equation

$$J_{a,b}\colon \begin{cases} ax^2 + y^2 = 1,\\ bx^2 + z^2 = 1,\end{cases}$$

where $ab(a - b) \neq 0$ [18]. It is known that some formulas of twisted Jacobi intersections can be computed using ω-coordinates defined as $\omega(x, y, z) = \sqrt{ab}x^2$ [22]. By the direct computation, we have

$$\operatorname{div} x = (O_{J_{a,b}}) + ((0,-1,1)) + ((0,1,-1)) + ((0,-1,-1)) - (\infty_1) - (\infty_2) - (\infty_3) - (\infty_4),$$

where $\infty_1, \ldots, \infty_4$ are points at infinity of $J_{a,b}$. We now show that $(\sqrt{ab}x^2)^{-1}$ is a normalized generalized Montgomery coordinate. From [18, Theorem 1] and some computations, there is an isomorphism

$$\begin{array}{rcl} E_M : v^2 = u^3 - \frac{a+b}{\sqrt{ab}}u^2 + u & \longrightarrow & J_{a,b}, \\ (u, v) & \longmapsto & \left(-\frac{2v}{\sqrt[4]{ab}(u^2-1)}, \frac{u^2-2\sqrt{\frac{a}{b}}u+1}{u^2-1}, \frac{u^2-2\sqrt{\frac{b}{a}}u+1}{u^2-1} \right). \end{array}$$

Therefore, ω-coordinate is the same as the function $\frac{4v^2}{(u^2-1)^2} = \frac{1}{(u\circ[2])(u,v)}$ on E_M. Since u is a normalized generalized Montgomery coordinate, ω^{-1} is also a normalized generalized Montgomery coordinate.

4 SCALAR MULTIPLICATION

In this section, we construct the formula of scalar multiplication via a generalized Montgomery coordinate and define the division polynomial of the generalized Montgomery coordinates. Basic pseudo-operations of a generalized Montgomery coordinate are given in Theorem 3 and Theorem 4. These theorems lead to the scalar multiplication algorithm on an elliptic curve using a generalized Montgomery coordinate using the same method as the Montgomery ladder [6, 14].

4.1 FORMULAS FOR SCALAR MULTIPLICATION

In this subsection, we fix a field K with characteristic other than 2, an elliptic curve E defined over $\overline{K}$, its subgroup $\mathcal{G}$, a point R_0 such that $R_0 \in \frac{1}{2}\mathcal{G} \setminus \mathcal{G}$, and the set $\mathcal{R}_0 = R_0 + \mathcal{G}$, and we let $h_{\mathcal{G},\mathcal{R}_0}$ be a normalized generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$.

We get the following theorems.

Theorem 3 (differential addition)**.** *Let P, Q be points of E such that $P \pm Q \notin \mathcal{G}$. Then, it holds that*

$$h_{\mathcal{G},\mathcal{R}_0}(P+Q)h_{\mathcal{G},\mathcal{R}_0}(P-Q) = \frac{(h_{\mathcal{G},\mathcal{R}_0}(Q)h_{\mathcal{G},\mathcal{R}_0}(P)-1)^2}{(h_{\mathcal{G},\mathcal{R}_0}(P)-h_{\mathcal{G},\mathcal{R}_0}(Q))^2}.$$

Theorem 4 (doubling)**.** *Let P be a point in E such that $2P \notin \mathcal{G}$. Then, it holds that*

$$h_{\mathcal{G},\mathcal{R}_0}(2P) = \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)-1)^2(h_{\mathcal{G},\mathcal{R}_0}(P)+1)^2}{4h_{\mathcal{G},\mathcal{R}_0}(P)\left(h_{\mathcal{G},\mathcal{R}_0}(P)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}}h_{\mathcal{G},\mathcal{R}_0}(P)+1\right)},$$

where $\alpha_{h_{\mathcal{G},\mathcal{R}_0}}$ is the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$ (Definition 2).

Before proving these theorems, we prove some lemmas.

Lemma 4. *It holds that*

$$h_{\mathcal{G},\mathcal{R}_0}(P+Q)h_{\mathcal{G},\mathcal{R}_0}(P-Q) = \frac{h_{\mathcal{G},\mathcal{R}_0}(Q)^2(h_{\mathcal{G},\mathcal{R}_0}(P)-h_{\mathcal{G},\mathcal{R}_0}(R_0+Q))^2}{(h_{\mathcal{G},\mathcal{R}_0}(P)-h_{\mathcal{G},\mathcal{R}_0}(Q))^2}.$$

Proof. We define the two maps ϕ_1 and ϕ_2 mapping from $E \times E$ to $\mathbb{P}^1$ as

$$\begin{aligned} \phi_1(P,Q) &= h_{\mathcal{G},\mathcal{R}_0}(P+Q)h_{\mathcal{G},\mathcal{R}_0}(P-Q), \\ \phi_2(P,Q) &= \frac{h_{\mathcal{G},\mathcal{R}_0}(Q)^2(h_{\mathcal{G},\mathcal{R}_0}(P)-h_{\mathcal{G},\mathcal{R}_0}(R_0+Q))^2}{(h_{\mathcal{G},\mathcal{R}_0}(P)-h_{\mathcal{G},\mathcal{R}_0}(Q))^2}. \end{aligned}$$

Suppose $Q \notin \mathcal{R}_0 \cup \mathcal{G}$. Let $\phi_{1,Q}(z) = \phi_1(z,Q)$ and $\phi_{2,Q}(z) = \phi_2(z,Q)$. By considering zero points and poles of $\phi_{1,Q}$ and $\phi_{2,Q}$, we have $\operatorname{div}\phi_{1,Q} = \operatorname{div}\phi_{2,Q}$. Therefore, there is a constant value c such that $\phi_{1,Q} = c \cdot \phi_{2,Q}$. We have $c = 1$ because

$$\begin{aligned} \phi_{1,Q}(R_0) &= h_{\mathcal{G},\mathcal{R}_0}(R_0+Q)h_{\mathcal{G},\mathcal{R}_0}(R_0-Q) = h_{\mathcal{G},\mathcal{R}_0}(R_0+Q)^2, \\ \phi_{2,Q}(R_0) &= h_{\mathcal{G},\mathcal{R}_0}(R_0+Q)^2. \end{aligned}$$

As $\mathcal{R}_0 \cup \mathcal{G}$ is a finite set, it holds that $\phi_1(P,z) = \phi_2(P,z)$ for a fixed point P. Therefore, we have $\phi_1 = \phi_2$. □

Lemma 5. *The set $\frac{1}{2}\mathcal{R}_0$ can be decomposed as follows:*

$$(\tilde{R}_0 + \mathcal{G}) \sqcup (\tilde{R}_0 + \mathcal{R}_0) \sqcup (\tilde{R}_0 + \mathcal{R}_1) \sqcup (\tilde{R}_0 + \mathcal{R}_0 + \mathcal{R}_1),$$

where $\tilde{R}_0$ is a point satisfying $2\tilde{R}_0 \in \mathcal{R}_0$, and $\mathcal{R}_1$ is the set defined in Lemma 1.

Moreover, one of the following holds:

- $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{G}) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_0) = \{1\}$ *and* $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_1) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_0 + \mathcal{R}_1) = \{-1\}$*;*
- $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{G}) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_0) = \{-1\}$ *and* $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_1) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + \mathcal{R}_0 + \mathcal{R}_1) = \{1\}$.

Proof. Because $E[2] \subset \frac{1}{2}\mathcal{G}$, we have $\frac{1}{2}\mathcal{R}_0 = \tilde{R}_0 + \frac{1}{2}\mathcal{G}$. From Lemma 1, the first part of Lemma 5 holds.

Let R_1 be a point in $\mathcal{R}_1$. By Lemma 3, we have

$$h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0)^2 = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_0)^2 = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_1)^2 = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_0 + R_1)^2 = 1.$$

Therefore, from Lemma 2,

$$h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_0) \text{ and } h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_1) = h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_0 + R_1).$$

Since the number of points in $h^{-1}_{\mathcal{G},\mathcal{R}_0}(z)$ for some $z \in \mathbb{P}^1$ is at most $2\#\mathcal{G}$, it holds that $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0+R_0) \neq h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0+R_1)$. From Theorem 1, this completes the proof of Lemma 5. □

Now, we prove Theorem 3 and Theorem 4.

Proof of Theorem 3. It follows from Lemma 4 and Lemma 2. □

Proof of Theorem 4. We define the two maps $\phi_1, \phi_2 \colon E \to \mathbb{P}^1$ as follows:

$$\begin{aligned}
\phi_1(z) &= h_{\mathcal{G},\mathcal{R}_0}(2z), \\
\phi_2(z) &= \frac{(h_{\mathcal{G},\mathcal{R}_0}(z) - 1)^2 (h_{\mathcal{G},\mathcal{R}_0}(z) + 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(z)(h_{\mathcal{G},\mathcal{R}_0}(z) - h_{\mathcal{G},\mathcal{R}_0}(R_1))(h_{\mathcal{G},\mathcal{R}_0}(z) - h_{\mathcal{G},\mathcal{R}_0}(R_0 + R_1))},
\end{aligned}$$

where R_1 is a point in $\mathcal{R}_1$. Note that the set of zero points of ϕ_1 is $\frac{1}{2}\mathcal{R}_0$, and the set of poles of ϕ_1 is $\frac{1}{2}\mathcal{G}$. Therefore, from Lemma 1 and Lemma 5, we have $\operatorname{div}\phi_1 = \operatorname{div}\phi_2$. Hence, it holds that $\phi_1 = c \cdot \phi_2$, where c is a constant value.

From Theorem 3, it holds that

$$h_{\mathcal{G},\mathcal{R}_0}(4z) h_{\mathcal{G},\mathcal{R}_0}(2z) = \frac{(h_{\mathcal{G},\mathcal{R}_0}(3z) h_{\mathcal{G},\mathcal{R}_0}(z) - 1)^2}{(h_{\mathcal{G},\mathcal{R}_0}(3z) - h_{\mathcal{G},\mathcal{R}_0}(z))^2}.$$

Note that $\alpha_{h_{\mathcal{G},\mathcal{R}_0}} = -(h_{\mathcal{G},\mathcal{R}_0}(R_1) + h_{\mathcal{G},\mathcal{R}_0}(R_0 + R_1))$. We also have

$$\begin{aligned}
h_{\mathcal{G},\mathcal{R}_0}(4z) h_{\mathcal{G},\mathcal{R}_0}(2z) &= c \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(2z)^2 - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(2z)(h_{\mathcal{G},\mathcal{R}_0}(2z)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}} h_{\mathcal{G},\mathcal{R}_0}(2z) + 1)} \cdot h_{\mathcal{G},\mathcal{R}_0}(2z) \\
&= c \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(2z)^2 - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(2z)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}} h_{\mathcal{G},\mathcal{R}_0}(2z) + 1}.
\end{aligned}$$

Using Theorem 3 again, we get

$$h_{\mathcal{G},\mathcal{R}_0}(3z) h_{\mathcal{G},\mathcal{R}_0}(z) = \frac{(h_{\mathcal{G},\mathcal{R}_0}(2z) h_{\mathcal{G},\mathcal{R}_0}(z) - 1)^2}{(h_{\mathcal{G},\mathcal{R}_0}(2z) - h_{\mathcal{G},\mathcal{R}_0}(z))^2}.$$

Therefore, it holds that

$$c \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(2z)^2 - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(2z)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}} h_{\mathcal{G},\mathcal{R}_0}(2z) + 1} = \frac{\left(\frac{(h_{\mathcal{G},\mathcal{R}_0}(2z) h_{\mathcal{G},\mathcal{R}_0}(z) - 1)^2}{(h_{\mathcal{G},\mathcal{R}_0}(2z) - h_{\mathcal{G},\mathcal{R}_0}(z))^2} - 1\right)^2 h_{\mathcal{G},\mathcal{R}_0}(z)^2}{\left(\frac{(h_{\mathcal{G},\mathcal{R}_0}(2z) h_{\mathcal{G},\mathcal{R}_0}(z) - 1)^2}{(h_{\mathcal{G},\mathcal{R}_0}(2z) - h_{\mathcal{G},\mathcal{R}_0}(z))^2} - h_{\mathcal{G},\mathcal{R}_0}(z)^2\right)^2}.$$

The right-hand side of this identity can be transformed as follows:

$$\begin{aligned}&\frac{\left((h_{\mathcal{G},\mathcal{R}_0}(2z)h_{\mathcal{G},\mathcal{R}_0}(z)-1)^2-(h_{\mathcal{G},\mathcal{R}_0}(2z)-h_{\mathcal{G},\mathcal{R}_0}(z))^2\right)^2 h_{\mathcal{G},\mathcal{R}_0}(z)^2}{\left((h_{\mathcal{G},\mathcal{R}_0}(2z)h_{\mathcal{G},\mathcal{R}_0}(z)-1)^2-(h_{\mathcal{G},\mathcal{R}_0}(2z)-h_{\mathcal{G},\mathcal{R}_0}(z))^2 h_{\mathcal{G},\mathcal{R}_0}(z)^2\right)^2}\\ =&\frac{(h_{\mathcal{G},\mathcal{R}_0}(2z)^2-1)^2 h_{\mathcal{G},\mathcal{R}_0}(z)^2}{(2h_{\mathcal{G},\mathcal{R}_0}(2z)h_{\mathcal{G},\mathcal{R}_0}(z)-h_{\mathcal{G},\mathcal{R}_0}(z)^2-1)^2}.\end{aligned}$$

Hence, we have

$$c\cdot\frac{1}{h_{\mathcal{G},\mathcal{R}_0}(2z)^2+\alpha_{h_{\mathcal{G},\mathcal{R}_0}}h_{\mathcal{G},\mathcal{R}_0}(2z)+1}=\frac{h_{\mathcal{G},\mathcal{R}_0}(z)^2}{(2h_{\mathcal{G},\mathcal{R}_0}(2z)h_{\mathcal{G},\mathcal{R}_0}(z)-h_{\mathcal{G},\mathcal{R}_0}(z)^2-1)^2}.$$

Let $\tilde{R}_0$ be a point satisfying $2\tilde{R}_0\in\mathcal{R}_0$. Note that $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0)=\pm1$, and $h_{\mathcal{G},\mathcal{R}_0}(2\tilde{R}_0)=0$. By substituting $\tilde{R}_0$ for z, we get $c=\frac{1}{4}$. □

4.2 DIVISION POLYNOMIALS OF THE GENERALIZED MONTGOMERY COORDINATES

In this subsection, we define the division polynomials of the generalized Montgomery coordinates. This definition is not the same as that of standard division polynomials. In fact, there appears x and y-coordinates in the standard division polynomials, while our division polynomials are represented by one-coordinate systems. However, both our m-th division polynomials and standard ones are minimal polynomials holding all information of m-torsion points. Thus, in this meaning, they are essentially the same.

Before defining the division polynomials, we need the following proposition which can be proven by induction.

Proposition 1. *Let $\Psi=4(h^2+\alpha h+1)\in\mathbb{Z}[\alpha,h]$. For any $m\in\mathbb{Z}_{\geq1}$, there exist polynomials $\Phi_m,\Psi_m\in\mathbb{Z}[\alpha,h]$ such that, for any elliptic curve E and any normalized generalized Montgomery coordinate $h_{\mathcal{G},\mathcal{R}_0}$, the following three properties hold: If m is odd,*

- *It holds that*
$$h_{\mathcal{G},\mathcal{R}_0}(mP)=\frac{h_{\mathcal{G},\mathcal{R}_0}(P)\Phi_m^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))}{\Psi_m^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))};$$
- *The highest term of $\Phi_m(\alpha,h)$ in the variable h is $h^{\frac{m^2-1}{2}}$;*
- *The highest term of $\Psi_m(\alpha,h)$ in the variable h is $m\cdot h^{\frac{m^2-1}{2}}$.*

If m is even,

- *It holds that*
$$h_{\mathcal{G},\mathcal{R}_0}(mP)=\frac{\Phi_m^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi_m^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))\cdot\Psi(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))};$$
- *The highest term of $\Phi_m(\alpha,h)$ in the variable h is $h^{\frac{m^2}{2}}$;*
- *The highest term of $\Psi_m(\alpha,h)$ in the variable h is $\frac{m}{2}\cdot h^{\frac{m^2-4}{2}}$.*

Here, $\alpha_{h_{\mathcal{G},\mathcal{R}_0}}$ is the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$.

Proof. We prove this proposition by mathematical induction. In the case of $m=1$, we have $\Phi_1(\alpha,h)=1$, and $\Psi_1(\alpha,h)=1$. In the case of $m=2$, from Theorem 4, we have $\Phi_2(\alpha,h)=h^2-1$, and $\Psi_2(\alpha,h)=1$. Let s be an odd integer greater than or equal to one. Suppose that Proposition 1 holds for $m=s$ and $m=s+1$. From Theorem 3, it holds that

$$\begin{aligned}h_{\mathcal{G},\mathcal{R}_0}((2s+1)P)&=\frac{(h_{\mathcal{G},\mathcal{R}_0}(sP)h_{\mathcal{G},\mathcal{R}_0}((s+1)P)-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)(h_{\mathcal{G},\mathcal{R}_0}(sP)-h_{\mathcal{G},\mathcal{R}_0}((s+1)P))^2}\\&=\frac{h_{\mathcal{G},\mathcal{R}_0}(P)(\Phi_s^2\Phi_{s+1}^2-\Psi_s^2\Psi_{s+1}^2\Psi)^2}{(h_{\mathcal{G},\mathcal{R}_0}(P)^2\Phi_s^2\Psi_{s+1}^2\Psi-\Phi_{s+1}^2\Psi_s^2)^2}.\end{aligned}$$

In this proof, as in the equation above, we often omit $(\alpha_{h_{\mathcal{G},\mathcal{R}_0}},h_{\mathcal{G},\mathcal{R}_0}(P))$. We define

$$\begin{aligned}\Phi_{2s+1}(\alpha,h)&=\Phi_s(\alpha,h)^2\Phi_{s+1}(\alpha,h)^2-\Psi_s(\alpha,h)^2\Psi_{s+1}(\alpha,h)^2\Psi(\alpha,h),\\\Psi_{2s+1}(\alpha,h)&=h^2\Phi_s(\alpha,h)^2\Psi_{s+1}(\alpha,h)^2\Psi(\alpha,h)-\Phi_{s+1}(\alpha,h)^2\Psi_s(\alpha,h)^2.\end{aligned}$$

It is easy to show that the highest term of $\Phi_{2s+1}(\alpha, h)$ in the variable h is $h^{\frac{(2s+1)^2-1}{2}}$, and that of $\Psi_{2s+1}(\alpha, h)$ in the variable h is $(2s+1) \cdot h^{\frac{(2s+1)^2-1}{2}}$. Therefore, Proposition 1 holds for $m = 2s+1$ for odd s. From Theorem 4, it holds that

$$\begin{aligned} h_{\mathcal{G},\mathcal{R}_0}(2sP) &= \frac{h_{\mathcal{G},\mathcal{R}_0}(2P)\Phi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(2P))}{\Psi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(2P))} \\ &= \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi} \frac{\Phi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi}) \cdot (h_{\mathcal{G},\mathcal{R}_0}(P)\Psi)^{s^2-1}}{\Psi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi}) \cdot (h_{\mathcal{G},\mathcal{R}_0}(P)\Psi)^{s^2-1}}. \end{aligned}$$

We define

$$\begin{aligned} \Phi_{2s}(\alpha, h) &= (h^2-1)(\Phi_s(\alpha, (h^2-1)^2/(h\Psi(\alpha, h))) \cdot (h\Psi(\alpha, h))^{\frac{s^2-1}{2}}), \\ \Psi_{2s}(\alpha, h) &= \Psi_s(\alpha, (h^2-1)^2/(h\Psi(\alpha, h))) \cdot (h\Psi(\alpha, h))^{\frac{s^2-1}{2}}. \end{aligned}$$

It is easy to show that the highest term of $\Phi_{2s}(\alpha, h)$ in the variable h is $h^{\frac{(2s)^2}{2}}$, and that of $\Psi_{2s}(\alpha, h)$ in the variable h is $s \cdot h^{\frac{(2s)^2-4}{2}}$. Therefore, Proposition 1 holds for $m = 2s$ for odd s.

Next, we consider the case that s is even. Suppose that Proposition 1 holds for $m = s$ and $m = s+1$. From Theorem 3, it holds that

$$h_{\mathcal{G},\mathcal{R}_0}((2s+1)P) = \frac{h_{\mathcal{G},\mathcal{R}_0}(P)(\Phi_s^2\Phi_{s+1}^2 - \Psi_s^2\Psi_{s+1}^2\Psi)^2}{(h_{\mathcal{G},\mathcal{R}_0}(P)^2\Phi_{s+1}^2\Psi_s^2\Psi - \Phi_s^2\Psi_{s+1}^2)^2}.$$

We define

$$\begin{aligned} \Phi_{2s+1}(\alpha, h) &= \Phi_s(\alpha, h)^2\Phi_{s+1}(\alpha, h)^2 - \Psi_s(\alpha, h)^2\Psi_{s+1}(\alpha, h)^2\Psi(\alpha, h), \\ \Psi_{2s+1}(\alpha, h) &= \Phi_s(\alpha, h)^2\Psi_{s+1}(\alpha, h)^2 - h^2\Phi_{s+1}(\alpha, h)^2\Psi_s(\alpha, h)^2\Psi(\alpha, h). \end{aligned}$$

It is easy to show that the highest term of Φ_{2s+1} in the variable h is $h^{\frac{(2s+1)^2-1}{2}}$, and that of Ψ_{2s+1} in the variable h is $(2s+1) \cdot h^{\frac{(2s+1)^2-1}{2}}$. Therefore, Proposition 1 holds for $m = 2s+1$ for even s. From Theorem 4, it holds that

$$\begin{aligned} h_{\mathcal{G},\mathcal{R}_0}(2sP) &= \frac{\Phi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(2P))}{h_{\mathcal{G},\mathcal{R}_0}(2P)\Psi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(2P))\Psi(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(2P))} \\ &= \frac{\Phi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi})}{\frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi} \cdot \Psi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi}) \cdot \Psi(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi})}, \end{aligned}$$

Note that

$$\begin{aligned} &\Psi\left(\alpha, \frac{(h^2-1)^2}{h\Psi}\right) \cdot h^2\Psi^2 \\ &= 4 \cdot ((h^2-1)^4 + \alpha(h^2-1)^2h\Psi + h^2\Psi^2) \\ &= 4 \cdot ((h^2-1)^4 + \alpha(h^2-1)^2h \cdot 4(h^2+\alpha h+1) + h^2 \cdot 16(h^2+\alpha h+1)^2) \\ &= 4 \cdot (h^4 + 2\alpha h^3 + 6h^2 + 2\alpha h + 1)^2. \end{aligned}$$

Therefore, $h_{\mathcal{G},\mathcal{R}_0}(2sP)$ is equal to

$$\frac{1}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi} \frac{\Phi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi}) \cdot (h_{\mathcal{G},\mathcal{R}_0}(P)\Psi)^{s^2}}{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2\Psi_s^2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)^2-1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)\Psi}) \cdot \tilde{\Psi}^2 \cdot (h_{\mathcal{G},\mathcal{R}_0}(P)\Psi)^{s^2-4}},$$

where $\tilde{\Psi}(\alpha, h)$ is a polynomial

$$\tilde{\Psi}(\alpha, h) = 2(h^4 + 2\alpha h^3 + 6h^2 + 2\alpha h + 1).$$

We define

$$\Phi_{2s}(\alpha, h) = \Phi_s(\alpha, (h^2-1)^2/(h\Psi(\alpha,h))) \cdot (h\Psi(\alpha,h))^{\frac{s^2}{2}},$$
$$\Psi_{2s}(\alpha, h) = (h^2-1) \cdot \Psi_s(\alpha, (h^2-1)^2/(h\Psi(\alpha,h))) \cdot \tilde{\Psi}(\alpha,h) \cdot (h\Psi(\alpha,h))^{\frac{s^2-4}{2}}.$$

It is easy to show that the highest term of $\Phi_{2s}(\alpha, h)$ in the variable h is $h^{\frac{(2s)^2}{2}}$, and that of $\Psi_{2s}(\alpha, h)$ in the variable h is $s \cdot h^{\frac{(2s)^2-4}{2}}$. Therefore, Proposition 1 holds for $m = 2s$ for even s. This completes the proof of Proposition 1. □

Now, we define the division polynomials of the generalized Montgomery coordinates.

Definition 4 (Division polynomials of the generalized Montgomery coordinates)**.** *Let $m \in \mathbb{Z}_{\geq 1}$, and let Ψ_m and Ψ be polynomials defined in the proof of Proposition 1. We define a polynomial $\psi'_m \in \mathbb{Z}[\alpha, h]$ as*

$$\psi'_m(\alpha, h) = \begin{cases} \Psi_m(\alpha, h) & (m \text{ is odd}), \\ h \cdot \Psi_m(\alpha, h) \cdot \Psi(\alpha, h) & (m \text{ is even}). \end{cases}$$

We define a polynomial $\psi_m \in \mathbb{Z}[\alpha, h]$ as $\psi_m = \psi'_m/d$, where d is the maximal integer such that ψ'_m/d is in $\mathbb{Z}[\alpha, h]$. That is, ψ_m is primitive. We call the polynomial ψ_m the m-th division polynomial of the generalized Montgomery coordinates.

The following theorem reveals the identity of division polynomials of the generalized Montgomery coordinates. That is, the m-th division polynomial of the generalized Montgomery coordinates is the most basic polynomial that has information on images of all points of order m of any elliptic curves under their generalized Montgomery coordinates. This identity provides the condition for the equality of the computational results of different formulas (Theorem 10).

Theorem 5. *Let p be the characteristic of $\overline{K}$, and let $m \in \mathbb{Z}_{\geq 1}$ satisfy $p \nmid m$ if $p \neq 0$. We define an ideal I_m in a polynomial ring $\mathbb{Z}[\alpha, h]$ as follows:*

$$I_m = \{\psi \mid \psi(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(P)) = 0 \in \overline{K} \text{ for all } (E, h_{\mathcal{G},\mathcal{R}_0}) \text{ and } P \in E[m] \setminus \mathcal{G}\}.$$

Then, it holds that I_m is generated by p and ψ_m, where ψ_m is the m-th division polynomial of the generalized Montgomery coordinates.

Proof. First, we consider the case of $p > 0$. It is clear that $p \in I_m$. Therefore, we prove that $\overline{\psi_m}\mathbb{F}_p[\alpha, h] = \overline{I_m}$, where $\overline{\psi_m}$ is the image of ψ_m under the canonical map $\mathbb{Z}[\alpha, h] \to \mathbb{F}_p[\alpha, h]$, and $\overline{I_m}$ is the ideal generated by an image of I_m under the canonical map $\mathbb{Z}[\alpha, h] \to \mathbb{F}_p[\alpha, h]$. Because $p \nmid m$, we have $\overline{\psi_m} \neq 0$ from Proposition 1. We define the ideal J_m of $\mathbb{F}_p(\alpha)[h]$ as

$$\left\{ \psi \in \mathbb{F}_p(\alpha)[h] \;\middle|\; \begin{array}{l} \exists f \in \mathbb{F}_p[\alpha] \setminus \{0\} \text{ s.t. } (f \cdot \psi)(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(P)) = 0 \\ \text{for all } (E, h_{\mathcal{G},\mathcal{R}_0}) \text{ and } P \in E[m] \setminus \mathcal{G} \end{array} \right\}.$$

Since $\mathbb{F}_p(\alpha)$ is a field, J_m is a principal ideal. We now prove that $J_m = \overline{\psi_m}\mathbb{F}_p(\alpha)[h]$. From the construction of ψ_m, it is clear that $\overline{\psi_m} \in J_m$. Suppose that $\overline{\psi_m}$ is not a generator of J_m. Then, there is a polynomial ψ_0 such that $\deg_h \psi_0 < \deg_h \overline{\psi_m}$ and $J_m = \psi_0\mathbb{F}_p(\alpha)[h]$. We now find a lower bound of $\deg_h \psi_0$. Note that it holds that $\deg_h \psi_0(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h) \leq \deg_h \psi_0$ for any $(E, h_{\mathcal{G},\mathcal{R}_0})$. Let $h_{\mathcal{G},\mathcal{R}_0}$ be a normalized generalized Montgomery coordinate with respect to $\{O_E\}$ (*e.g.,* x-coordinates of Montgomery curves). By the definition of J_m, elements in $h_{\mathcal{G},\mathcal{R}_0}(E[m] \setminus \{O_E\})$ are the roots of $(f \cdot \psi_0)(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h)$ for some $f \in \mathbb{F}_p[\alpha] \setminus \{0\}$. We redefine ψ_0 as $f \cdot \psi_0$. Note that all elements in $\overline{K} \setminus \{\pm 2\}$ can be a Montgomery coefficient of some elliptic curve. Changing E if necessary, we may assume that $\psi_0(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h) \neq 0$. Therefore, we have $\deg_h \psi_0(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h)$ is larger than $\#h_{\mathcal{G},\mathcal{R}_0}(E[m] \setminus \{O_E\})$. Note that $\#h_{\mathcal{G},\mathcal{R}_0}(E[m] \setminus \{O_E\})$ is $\frac{m^2-1}{2}$ if m is odd, and it is $\frac{m^2-4}{2} + \#(E[2] \setminus \{O_E\}) = \frac{m^2+2}{2}$ if m is even. Therefore, from Proposition 1, it holds that $\deg_h \overline{\psi_m}$ is the number of elements in $h_{\mathcal{G},\mathcal{R}_0}(E[m] \setminus \{O_E\})$. However, we have $\deg_h \psi_0(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h) \leq \deg_h \psi_0 < \deg_h \overline{\psi_m}$. This is a contradiction. Hence, it holds that $J_m = \overline{\psi_m}\mathbb{F}_p(\alpha)[h]$.

Let ψ be a polynomial in $\overline{I_m}$. It is easy to see that $\psi \in J_m = \overline{\psi_m}\mathbb{F}_p(\alpha)[h]$. Therefore, $\psi/\overline{\psi_m}$ is in $\mathbb{F}_p(\alpha)[h]$. We denote $\psi/\overline{\psi_m}$ by $F(\alpha, h)$. From Proposition 1, we get that the coefficient of the highest term in the variable h of $\overline{\psi_m}$ is in $\mathbb{F}_p \setminus \{0\}$. Therefore, $\overline{\psi_m}$ is primitive as a polynomial in $(\mathbb{F}_p[\alpha])[h]$. Note that $\psi \in \mathbb{F}_p[\alpha, h]$. From Gauss's Lemma, we have $F(\alpha, h) \in \mathbb{F}_p[\alpha, h]$. Therefore, $\psi \in \overline{\psi_m}\mathbb{F}_p[\alpha, h]$. In other words, it holds that $\overline{I_m} \subset \overline{\psi_m}\mathbb{F}_p[\alpha, h]$. Because it is clear that $\overline{\psi_m} \in \overline{I_m}$, we have $\overline{I_m} = \overline{\psi_m}\mathbb{F}_p[\alpha, h]$. This completes the proof of the case of $p > 0$.

We now consider the case of $p = 0$. We can prove the most part by changing $\mathbb{F}_p[\alpha, h]$ to $\mathbb{Q}[\alpha, h]$ and having a similar discussion. The rest is the part that proves $F(\alpha, h) \in \mathbb{Z}[\alpha, h]$, where $F(\alpha, h)$ is a polynomial in $\mathbb{Q}(\alpha)[h]$ such that $F(\alpha, h) = \psi/\psi_m$ for some $\psi \in I_m$. Remember that ψ_m is primitive by its definition. From Gauss's Lemma, $F(\alpha, h) \in \mathbb{Z}[\alpha, h]$. □

5 ISOGENY COMPUTATION

In this section, we construct formulas to compute isogenies via a generalized Montgomery coordinate. Throughout this section, we fix an elliptic curve E defined over $\overline{K}$, its subgroup $\mathcal{G}$, a point R_0 such that $R_0 \notin \mathcal{G}$ and $2R_0 \in \mathcal{G}$, and the set $\mathcal{R}_0 = R_0 + \mathcal{G}$, and we let $h_{\mathcal{G},\mathcal{R}_0}$ be a normalized generalized Montgomery coordinate with respect to $\mathcal{G}$ and $\mathcal{R}_0$.

To compute isogenies, we need two formulas: the formula to compute an image point under the isogeny and the formula to compute the coefficient of the codomain elliptic curve. In the subsection 5.1, we construct the first formula, and in the subsection 5.2, we construct one of the second formulas. The second formulas are known to be of various types. In subsection 5.3, we explain that this difference comes from the division polynomial of the generalized Montgomery coordinates.

5.1 FORMULA FOR IMAGE POINTS

In this subsection, we explain the formula for computing image points under isogenies using a generalized Montgomery coordinate.

Theorem 6 (odd degree isogeny)**.** *Let G be a finite subgroup of E satisfying*

$$G \cap (\mathcal{G} \cup \mathcal{R}_0) = \{O_E\}.$$

Let ϕ be a separable isogeny $\phi\colon E \to E/G$ with $\ker\phi = G$. Then, there is a normalized generalized Montgomery coordinate of E/G with respect to $\phi(\mathcal{G})$ and $\phi(\mathcal{R}_0)$ satisfying

$$h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(\phi(P)) = h_{\mathcal{G},\mathcal{R}_0}(P) \prod_{Q \in G \setminus \{O_E\}} \frac{(h_{\mathcal{G},\mathcal{R}_0}(P)h_{\mathcal{G},\mathcal{R}_0}(Q) - 1)}{(h_{\mathcal{G},\mathcal{R}_0}(P) - h_{\mathcal{G},\mathcal{R}_0}(Q))}.$$

Proof. We define a map $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)} \in \overline{K}(E/G)$ satisfying

$$\operatorname{div} h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)} = 2\sum_{R \in \phi(\mathcal{R}_0)} (R) - 2\sum_{P \in \phi(\mathcal{G})} (P).$$

It is clear that $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ is a generalized Montgomery coordinate of E/G with respect to $\phi(\mathcal{G})$ and $\phi(\mathcal{R}_0)$. By multiplying by a constant value, we can assume that $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ is normalized. Let $\tilde{R}_0$ be a point of E satisfying $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0) = 1$. Note that $h_{\mathcal{G},\mathcal{R}_0}(2\tilde{R}_0) = 0$ from Theorem 1 and Lemma 5. We have $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(2\phi(\tilde{R}_0)) = 0$. Therefore, by Lemma 5, $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(\phi(\tilde{R}_0)) = \pm 1$. If this value is -1, we multiply $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ by -1. We define two maps $\phi_1, \phi_2 \in \overline{K}(E)$ as

$$\begin{aligned}
\phi_1(z) &= h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(\phi(z)),\\
\phi_2(z) &= h_{\mathcal{G},\mathcal{R}_0}(z) \prod_{Q \in G \setminus \{O_E\}} \frac{(h_{\mathcal{G},\mathcal{R}_0}(z)h_{\mathcal{G},\mathcal{R}_0}(Q) - 1)}{(h_{\mathcal{G},\mathcal{R}_0}(z) - h_{\mathcal{G},\mathcal{R}_0}(Q))}.
\end{aligned}$$

It is easy to check that $\operatorname{div}\phi_1 = \operatorname{div}\phi_2$. Since $\phi_1(\tilde{R}_0) = \phi_2(\tilde{R}_0) = 1$, it holds that $\phi_1 = \phi_2$. This completes the proof of Theorem 6. □

Theorem 6 gives us the formula for computing an isogeny whose kernel is G, which satisfies $G \cap (\mathcal{G} \cup \mathcal{R}_0) = \{O_E\}$. If $E[2] \setminus \mathcal{G} \neq \emptyset$, and R_0 is a point of order 2 with $R_0 \notin \mathcal{G}$, then we can construct the natural formula of a 2-isogeny whose kernel is $\langle R_0 \rangle$.

Theorem 7 (2-isogeny)**.** *We assume that $E[2] \setminus \mathcal{G} \neq \emptyset$, and R_0 is a point of order 2 with $R_0 \notin \mathcal{G}$. Let $G = \langle R_0 \rangle$, and let $\phi\colon E \to E/G$ be a separable isogeny with $\ker\phi = G$. Then, there are six normalized generalized Montgomery coordinates of E/G with respect to $\phi(\mathcal{G})$ satisfying the following equalities:*

$$\begin{aligned}
h_{1,\pm}(\phi(P)) &= \pm\frac{1}{2\sqrt{\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}} \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(P) - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)},\\
h_{2,\pm}(\phi(P)) &= \pm\frac{1}{2\sqrt{-\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}} \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(P) + 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)},\\
h_{3,\pm}(\phi(P)) &= \pm\frac{1}{\sqrt{\alpha^2_{h_{\mathcal{G},\mathcal{R}_0}} - 4}} \cdot \frac{h_{\mathcal{G},\mathcal{R}_0}(P)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}} h_{\mathcal{G},\mathcal{R}_0}(P) + 1}{h_{\mathcal{G},\mathcal{R}_0}(P)},
\end{aligned}$$

where $\alpha_{h_{\mathcal{G},\mathcal{R}_0}}$ is the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$.

Proof. Let $\mathcal{R}_1$ be the set defined in Lemma 1, let R_1 be a point in $\mathcal{R}_1$, and let $\tilde{R}_0$ be a point satisfying $2\tilde{R}_0 = R_0$. One can check that $2\phi(\tilde{R}_0) \in \phi(\mathcal{G})$ and $\phi(\tilde{R}_0) \notin \phi(\mathcal{G}) \cup \phi(\mathcal{R}_1)$. Therefore, from Lemma 1, we have

$$\frac{1}{2}\phi(\mathcal{G}) = \phi(\mathcal{G}) \sqcup \phi(\mathcal{R}_1) \sqcup (\phi(\tilde{R}_0) + \phi(\mathcal{G})) \sqcup (\phi(\tilde{R}_0) + \phi(\mathcal{R}_1)).$$

Hence, we get the following normalized generalized Montgomery coordinates:

- $h_{1,+}$ and $h_{1,-}$ with respect to $\phi(\mathcal{G})$ and $\phi(\tilde{R}_0) + \phi(\mathcal{G})$,
- $h_{2,+}$ and $h_{2,-}$ with respect to $\phi(\mathcal{G})$ and $\phi(\tilde{R}_0) + \phi(R_1) + \phi(\mathcal{G})$,
- $h_{3,+}$ and $h_{3,-}$ with respect to $\phi(\mathcal{G})$ and $\phi(R_1) + \phi(\mathcal{G})$,

where $h_{i,-} = -h_{i,+}$ for $i = 1, 2, 3$. Note that $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0 + R_1) = -1$ from Lemma 5. By considering zero points and poles, we have

$$\begin{aligned}
h_{1,\pm}(\phi(P)) &= \pm c_1 \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(P) - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)}, \\
h_{2,\pm}(\phi(P)) &= \pm c_2 \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(P) + 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(P)}, \\
h_{3,\pm}(\phi(P)) &= \pm c_3 \cdot \frac{h_{\mathcal{G},\mathcal{R}_0}(P)^2 + \alpha_{h_{\mathcal{G},\mathcal{R}_0}} h_{\mathcal{G},\mathcal{R}_0}(P) + 1}{h_{\mathcal{G},\mathcal{R}_0}(P)},
\end{aligned}$$

where c_1, c_2, and c_3 are constant values of $\overline{K}$.

Next, we find these constant values. From Lemma 2, it holds that

$$h_1(\phi(\tilde{R}_0) + \phi(R_1)) \cdot h_1(\phi(R_1)) = 1.$$

Therefore, it holds that

$$c_1^2 \cdot (-4) \cdot \frac{(h_{\mathcal{G},\mathcal{R}_0}(R_1) - 1)^2}{h_{\mathcal{G},\mathcal{R}_0}(R_1)} = 1.$$

Thus, we have $c_1 = \frac{1}{2\sqrt{\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}}$. It also holds that

$$h_2(\phi(\tilde{R}_0)) \cdot h_2(\phi(R_1)) = 1.$$

Therefore, by a similar calculation, we also have $c_2 = \frac{1}{2\sqrt{-\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}}$. It also holds that

$$h_3(\phi(\tilde{R}_0) + \phi(R_1)) \cdot h_3(\phi(\tilde{R}_0)) = 1.$$

Hence, we also have $c_3 = \frac{1}{\sqrt{\alpha_{h_{\mathcal{G},\mathcal{R}_0}}^2 - 4}}$. This completes the proof of Theorem 7. □

5.2 FORMULA FOR GENERALIZED MONTGOMERY COEFFICIENTS

In this subsection, we construct a formula to compute generalized Montgomery coefficients of target curves of isogenies by Theorem 6. The following theorem gives the formula, which corresponds to the formula constructed from the 2-torsion method proposed in [13].

Theorem 8 (odd degree isogeny)**.** *Let $\mathcal{R}_1$ be a subset of E defined in Lemma 1, let R_1 be a point in $\mathcal{R}_1$, and let G be a subgroup of E satisfying*

$$G \cap (\mathcal{G} \cup \mathcal{R}_0 \cup \mathcal{R}_1) = \{O_E\}.$$

Let ϕ be a separable isogeny $\phi\colon E \to E/G$ with $\ker\phi = G$, and let $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ be a normalized generalized Montgomery coordinate of E/G that is defined in Theorem 6. Then, the generalized Montgomery coefficient of $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ is

$$\begin{aligned}
\alpha_{h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}} = &- h_{\mathcal{G},\mathcal{R}_0}(R_1) \prod_{Q \in G \setminus \{O_E\}} \frac{(h_{\mathcal{G},\mathcal{R}_0}(R_1) h_{\mathcal{G},\mathcal{R}_0}(Q) - 1)}{(h_{\mathcal{G},\mathcal{R}_0}(R_1) - h_{\mathcal{G},\mathcal{R}_0}(Q))} \\
&- \frac{1}{h_{\mathcal{G},\mathcal{R}_0}(R_1)} \prod_{Q \in G \setminus \{O_E\}} \frac{(h_{\mathcal{G},\mathcal{R}_0}(R_1) - h_{\mathcal{G},\mathcal{R}_0}(Q))}{(h_{\mathcal{G},\mathcal{R}_0}(R_1) h_{\mathcal{G},\mathcal{R}_0}(Q) - 1)}.
\end{aligned}$$

Proof. Because $2\phi(R_1) = \phi(2R_1) \in \phi(\mathcal{G})$ and $R_1 \notin G$, the generalized Montgomery coefficient of $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ is

$$-h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(\phi(R_1)) - \frac{1}{h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}(\phi(R_1))}.$$

Theorem 6 completes the proof. □

Theorem 9 (2-isogeny)**.** *Assume that $E[2] \setminus \mathcal{G} \neq \emptyset$, and R_0 is a point of order 2 with $R_0 \notin \mathcal{G}$. Let $G = \langle R_0 \rangle$, and let $\phi\colon E \to E/G$ be a separable isogeny with $\ker\phi = G$. Let $h_{1,\pm}$, $h_{2,\pm}$, and $h_{3,\pm}$ be normalized generalized Montgomery coordinates in Theorem 7. Then, the generalized Montgomery coefficients of these generalized Montgomery coordinates are as follows:*

$$\alpha_{h_{1,\pm}} = \pm\frac{\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 6}{2\sqrt{\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}},\ \alpha_{h_{2,\pm}} = \pm\frac{\alpha_{h_{\mathcal{G},\mathcal{R}_0}} - 6}{2\sqrt{-\alpha_{h_{\mathcal{G},\mathcal{R}_0}} + 2}},\ \alpha_{h_{3,\pm}} = \mp\frac{2\alpha_{h_{\mathcal{G},\mathcal{R}_0}}}{\sqrt{\alpha^2_{h_{\mathcal{G},\mathcal{R}_0}} - 4}},$$

where $\alpha_{h_{\mathcal{G},\mathcal{R}_0}}$ is the generalized Montgomery coefficient of $h_{\mathcal{G},\mathcal{R}_0}$.

Proof. Most parts of the proof can be shown in the same way as the proof of Theorem 8. The remaining part is that of $\alpha_{h_{3,\pm}}$. Since $h_{3,\pm}(\phi(R_1)) = 0$, we cannot use the same discussion as the previous proofs. It is easy to see that a point $\phi(\tilde{R}_0)$ represents the generalized Montgomery coefficients of $h_{3,\pm}$, where $\tilde{R}_0$ is a point such that $2\tilde{R}_0 = R_0$. From the fact that $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0) = 1$ or $h_{\mathcal{G},\mathcal{R}_0}(\tilde{R}_0) = -1$, we get the formulas to compute the generalized Montgomery coefficients of $h_{3,\pm}$. This completes the proof of Theorem 9. □ □

5.3 DIFFERENCE OF SOME FORMULAS FOR GENERALIZED MONTGOMERY COEFFICIENTS

Now, we focus on the formulas for odd-degree isogenies. By considering the symmetry of the equality and formulas of scalar multiplications, we show that formulas in Theorem 8 can be represented by the ratio of two polynomials in $\mathbb{Z}[\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)]$. These formulas are correct; however, one may know that there are some different formulas to compute generalized Montgomery coefficients on Montgomery curves (*e.g.,* those proposed in [13], and those proposed in [33]). Thus, a question arises: Are these formulas generalized by formulas via a generalized Montgomery coordinate? The answer is yes. The following theorem claims that we can construct these formulas by considering division polynomials of the generalized Montgomery coordinates (Definition 4).

Theorem 10. *Let ℓ be an odd prime, and K be a field whose characteristic is neither 2 nor ℓ. Let E be an arbitrary elliptic curve defined over $\overline{K}$, $h_{\mathcal{G},\mathcal{R}_0}$ be its arbitrary normalized generalized Montgomery coordinate, Q be an arbitrary point of order ℓ in E, ϕ be a separable isogeny with $\ker\phi = \langle Q \rangle$, and $h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}$ be a normalized generalized Montgomery coordinate of $E/\langle Q \rangle$ defined in Theorem 6. Suppose that $\phi_1, \phi_2, \phi_3, \phi_4$ are polynomials in $\mathbb{Z}[\alpha, h]$ always satisfying $\phi_2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)) \neq 0$, $\phi_4(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)) \neq 0$, and*

$$\alpha_{h_{\phi(\mathcal{G}),\phi(\mathcal{R}_0)}} = \frac{\phi_1(\alpha_{h_{\mathcal{G}_E,\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q))}{\phi_2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q))} = \frac{\phi_3(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q))}{\phi_4(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q))}.$$

Then, it holds that if the characteristic of K is $p > 0$,

$$\frac{\phi_1(\alpha,h)}{\phi_2(\alpha,h)} - \frac{\phi_3(\alpha,h)}{\phi_4(\alpha,h)} \equiv \psi_\ell(\alpha,h)\cdot\frac{\varphi_1(\alpha,h)}{\varphi_2(\alpha,h)} \pmod{p},$$

and if the characteristic of K is 0,

$$\frac{\phi_1(\alpha,h)}{\phi_2(\alpha,h)} - \frac{\phi_3(\alpha,h)}{\phi_4(\alpha,h)} = \psi_\ell(\alpha,h)\cdot\frac{\varphi_1(\alpha,h)}{\varphi_2(\alpha,h)},$$

where ψ_ℓ is the ℓ-th division polynomial of the generalized Montgomery coordinates, and φ_1 and φ_2 are polynomials in $\mathbb{Z}[\alpha, h]$ such that $\varphi_2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)) \neq 0$ for all $(E, h_{\mathcal{G},\mathcal{R}_0})$ and Q.

Proof. Suppose that the characteristic of K is $p > 0$. We define $\phi(\alpha, h) \in \mathbb{Z}[\alpha, h]$ as

$$\phi(\alpha,h) = \phi_1(\alpha,h)\phi_4(\alpha,h) - \phi_2(\alpha,h)\phi_3(\alpha,h).$$

Then, it holds that $\phi(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)) = 0$ for all $(E, h_{\mathcal{G},\mathcal{R}_0})$ and $Q \in E[\ell] \setminus \{O_E\}$ because ℓ is a prime number. Therefore, from Theorem 5, there is a polynomial φ_1 in $\mathbb{Z}[\alpha, h]$ such that $\phi(\alpha,h) \equiv \psi_\ell(\alpha,h)\cdot\varphi_1(\alpha,h) \pmod{p}$. We define $\varphi_2 \in \mathbb{Z}[\alpha, h]$ as $\varphi_2(\alpha,h) = \phi_2(\alpha,h)\phi_4(\alpha,h)$. It is clear that $\varphi_2(\alpha_{h_{\mathcal{G},\mathcal{R}_0}}, h_{\mathcal{G},\mathcal{R}_0}(Q)) \neq 0$ for all $(E, h_{\mathcal{G},\mathcal{R}_0})$ and $Q \in E[\ell] \setminus \{O_E\}$. This completes the proof in the case that the characteristic of K is $p > 0$.

The case that the characteristic of K is 0 can be proved similarly. □

Remark 9. *In Theorem 10, we fix that ℓ is a prime number. However, if ℓ is not prime, similar theorems also hold. In these theorems, the parts of division polynomials of their equalities get slightly complicated.*

Example 1. *Let $\ell = 3$. We now consider the difference of the formula proposed in [38] and that proposed in [33]. The difference satisfies*

$$\begin{aligned}&(-6h^3 + \alpha h^2 + 6h) - \left(\frac{2((\alpha+2)^3(h+1)^8 + (\alpha-2)^3(h-1)^8)}{(\alpha+2)^3(h+1)^8 - (\alpha-2)^3(h-1)^8}\right)\\ &= (3h^4 + 4\alpha h^3 + 6h^2 - 1) \cdot \frac{4(6\alpha^2 h^7 + 8h^7 - \alpha^3 h^6 + \cdots - 40h - \alpha^3 - 12\alpha)}{(\alpha+2)^3(h+1)^8 - (\alpha-2)^3(h-1)^8}.\end{aligned}$$

It is easy to see that $3h^4+4\alpha h^3+6h^2-1$ is the 3-rd division polynomial of the generalized Montgomery coordinates.

From Theorem 10, the problem of constructing an efficient formula is reduced to the problem of finding a proper element in an ideal I_m defined in Theorem 5. As a simple application of this fact, we may find more efficient formulas by trying to add previous formulas and some elements in I_m. Moreover, we believe that we can use this consideration to estimate the lower bound of the cost of formulas of isogeny computation. This will be done in our future works.

6 APPLICATIONS OF A GENERALIZED MONTGOMERY COORDINATE

In this section, we explain two applications of a generalized Montgomery coordinate. The first is the construction of a new efficient formula to compute isogenies on Montgomery curves. The second is the construction of a new generalized Montgomery coordinate on Montgomery$^-$ curves that can be used to new CSURF algorithm.

6.1 NEW FORMULAS TO COMPUTE ISOGENIES ON MONTGOMERY CURVES

As discussed in subsection 3.3, the inverse of the w-coordinate on an Edwards curve is a normalized generalized Montgomery coordinate. Therefore, we know that formulas of Montgomery and Edwards curves are essentially the same. This insight results in a formula of x-coordinates from that of w-coordinates. Kim, Yoon, Park, and Hong proposed formulas to compute odd degree isogenies [29]. Let ℓ be an odd integer, and let P be a point of order ℓ. Let ϕ be an isogeny $E \to E/\langle P\rangle$ with $\ker\phi = \langle P\rangle$. Thus, we can compute an Edwards coefficient of $E/\langle P\rangle$, denoted by d', as follows [29]:

$$d' = d^\ell \prod_{k=1}^{s} \frac{(w(kP)+1)^8}{2^8},$$

where d is the Edwards coefficient of E, and s is an integer such that $\ell = 2s+1$. From the doubling formula of w-coordinates of Edwards curves in [17], we obtain the generalized Montgomery coefficient of w^{-1} as $2-4/d$. Hence, from Theorem 2, we obtain the isogeny $\phi\colon E \to F$ of degree 4 such that $x \circ \phi = w^{-1}$, where F is a Montgomery curve whose coefficient is $2-4/d$. Now, we can construct a new formula of Montgomery curves. Let ϕ' be an isogeny $F \to F/\langle Q\rangle$ with $\ker\phi' = \langle Q\rangle$, where Q is a point in F of order ℓ. Since ℓ is odd, we easily observe that the Montgomery coefficient of $F/\langle Q\rangle$ is $2-4/d'$. Note that for any $\alpha \in K \setminus \{\pm 2\}$, the curve

$$x^2 + y^2 = 1 + \frac{4}{2-\alpha}x^2y^2$$

is an Edwards curve, and its w-coordinate corresponds to the x-coordinate of the Montgomery curve $y^2 = x^3+\alpha x^2+x$. Thus, we can compute the Montgomery coefficient of $F/\langle Q\rangle$ denoted by α' as follows:

$$\frac{2-\alpha'}{4} = \left(\frac{2-\alpha}{4}\right)^\ell \prod_{k=1}^{s} \frac{(2x(kQ))^8}{(1+x(kQ))^8},$$

where α is the Montgomery coefficient of F. Moreover, by considering the quadratic twist, we can also construct the following formula:

$$\frac{\alpha'+2}{4} = \left(\frac{\alpha+2}{4}\right)^\ell \prod_{k=1}^{s} \frac{(2x(kQ))^8}{(1-x(kQ))^8}.$$

One may translate the formula of Edwards curves to Montgomery curves using an isomorphism between these curves. However, this process is more complicated than the construction using a generalized Montgomery coordinate. That is, by considering a generalized Montgomery coordinate, we can naturally transplant formulas.

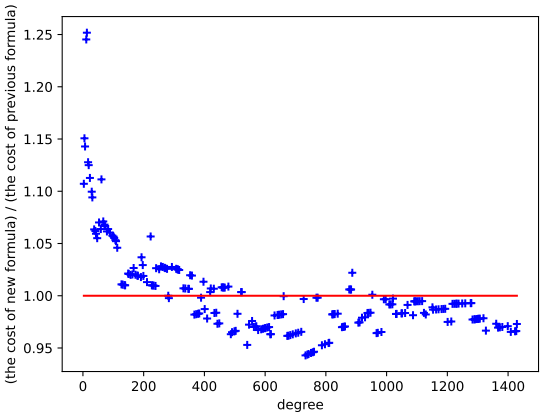

Figure 2: Ratio of the cost of our new formula to that of the previous formula

This formula is as efficient as that proposed by Meyer and Reith [33] for basic calculations. In addition, as the √élu's formula, this formula is more efficient than that proposed in [5]. The √élu's formula is a method of more efficiently computing large prime degree isogenies. In [5], Bernstein, De Feo, Leroux, and Smith first proposed the √élu's formula via x-coordinates of Montgomery curves. In this method, we calculate resultants of a polynomial of degree $2\lfloor\sqrt{\ell-1}/2\rfloor$ and a polynomial of degree about $\lfloor\sqrt{\ell-1}/2\rfloor$ to compute an ℓ-isogeny. In [35], Moriya, Onuki, and Takagi suggested that the √élu's formula via w-coordinates of Edwards curves is more efficient than the original √élu's formula for large degree isogenies. It is because one resultant in the computation on Edwards curves can be replaced by a resultant of two polynomials of degree about $\lfloor\sqrt{\ell-1}/2\rfloor$, which is a half degree in the computation on Montgomery curves. Since we can adapt the method of [35] to our new formula, this is more efficient than that proposed in [5] for large degree isogenies.

We implemented our new formula based on the SIBC Python library [2] in [1], and compared its cost to that obtained by the previous formula implemented by [2] at various prime degrees. The implementation results are in Figure 2. Here, we use the 4096-bits prime defined in [2] as p, and measured the number of multiplications and squarings in $\mathbb{F}_p$ as the cost. The vertical line shows the ratio of the cost of our new formula to that of the previous formula, and the horizontal line shows the degree of isogenies. That is, at the points below the line of 1.00, our new formula is more efficient than the previous one. Therefore, for large degree isogenies, our proposed formula is faster in terms of the number of multiplications and squarings in $\mathbb{F}_p$ in our implementation. In future study, we intend to confirm if this formula is faster than previous one when implemented in low-level programming languages (*e.g.*, C) in practice. Our source code is available from `http://tomoriya.work/code.html`.

6.2 NEW GENERALIZED MONTGOMERY COORDINATE TO COMPUTE ISOGENIES ON MONTGOMERY$^-$ CURVES

In this subsection, we construct a new normalized generalized Montgomery coordinate on a Montgomery$^-$ curve. Montgomery$^-$ curves are primarily used for CSURF [7]. This coordinate enables us to compute isogenies on Montgomery$^-$ curves using the same formulas for Montgomery curves.

Let E be a Montgomery$^-$ curve $y^2 = x^3 + \alpha x^2 - x$, and $(a, 0)$ and $(-1/a, 0)$ be points of order 2 other than $(0, 0)$. We obtain

$$\begin{aligned}\operatorname{div} x &= 2((0,0)) - 2(O_E),\\ \operatorname{div} y &= ((a,0)) + ((-1/a,0)) + ((0,0)) - 3(O_E).\end{aligned}$$

Therefore, it holds that

$$\operatorname{div}(y^2/x^2) = 2((a,0)) + 2((-1/a,0)) - 2((0,0)) - 2(O_E).$$

A direct calculation results in

$$\frac{y(P)^2}{x(P)^2}\cdot\frac{y(P+(a,0))^2}{x(P+(a,0))^2} = \frac{(a^2+1)^2}{a^2} = \alpha^2+4.$$

Therefore, $\frac{1}{\sqrt{\alpha^2+4}}y^2/x^2$ is a normalized generalized Montgomery coordinate on E with respect to $\langle(0,0)\rangle$ and $(a,0)$. Here, we use p that satisfies $p \equiv 3 \pmod 4$, and fix $\sqrt{\cdot}\colon \overline{\mathbb{F}_p} \to \overline{\mathbb{F}_p}$ such that $\sqrt{\cdot}|_{(\mathbb{F}_p)^2}\colon (\mathbb{F}_p)^2 \to \mathbb{F}_p$ to $\sqrt{A} = A^{\frac{p+1}{4}}$.

We denote $\frac{1}{\sqrt{\alpha^2+4}}y^2/x^2$ as w. Because the double of $(\sqrt{-1}, \sqrt{-\alpha-2\sqrt{-1}})$ is $(0,0)$, the generalized Montgomery coefficient of w is

$$\alpha_w = -w(\sqrt{-1}, \sqrt{-\alpha-2\sqrt{-1}}) - \frac{1}{w(\sqrt{-1}, \sqrt{-\alpha-2\sqrt{-1}})} = -\frac{2\alpha}{\sqrt{\alpha^2+4}}.$$

Remark 10. *If a supersingular elliptic curve E defined over $\mathbb{F}_p$ has the $\mathbb{F}_p$-endomorphism ring isomorphic to $\mathbb{Z}[\frac{\sqrt{-p}+1}{2}]$, we say E is on the surface, and if a supersingular elliptic curve E defined over $\mathbb{F}_p$ has the $\mathbb{F}_p$-endomorphism ring isomorphic to $\mathbb{Z}[\sqrt{-p}]$, we say E is on the floor.*

From Theorem 2, the w-coordinate of the Montgomery$^-$ curve can be represented by $w = x \circ \phi$, where ϕ is an isogeny with $\ker\phi = \langle(0,0)\rangle$. This isogeny is the 2-isogeny that maps an elliptic curve on the surface to that on the floor [7, Lemma 2].

Since $\#\langle(0,0)\rangle = 2$, we can compute isogenies of odd degrees of Montgomery$^-$ curves using the same formulas as on Montgomery curves via the w-coordinates. In [8], the authors mentioned that by considering an isogeny from Montgomery$^-$ curves to curves on the floor, the CSURF algorithm becomes more efficient because formulas on Montgomery curves are used. As Remark 10 indicates, this technique is the same as considering the w-coordinate of Montgomery$^-$ curves.

However, the calculation of 2-isogenies is not possible via the w-coordinates. Let $\phi\colon E \to E'$ be a 2-isogeny between Montgomery$^-$ curves with $\ker\phi = \langle(a,0)\rangle$. We denote the w-coordinates on E and E' as w_E and $w_{E'}$, respectively. Let us assume that there is a map $f\colon \mathbb{P}^1 \to \mathbb{P}^1$ such that $w_{E'}(\phi(P)) = f(w_E(P))$. As $w_E(P+(0,0)) = w_E(P)$, it holds that $f(w_E(P+(0,0))) = f(w_E(P))$. In contrast, because $\phi(0,0)$ is the back track point of ϕ (*i.e.,* $\ker\hat{\phi} = \langle\phi(0,0)\rangle$), it holds that $w_{E'}(\phi(P+(0,0))) = 1/w_{E'}(\phi(P))$. This is a contradiction. Therefore, we cannot compute $w_{E'}(P)$ using $w_E(P)$. However, we can compute the generalized Montgomery coefficient of $w_{E'}$ from that of w_E using the following theorems.

Theorem 11 (2-isogeny)**.** *Let $p \equiv 7 \pmod 8$, let E and E' be supersingular Montgomery$^-$ curves, and let $\phi\colon E \to E'$ be a 2-isogeny defined over $\mathbb{F}_p$ with $\ker\phi = \langle P\rangle$. We denote the w-coordinates on E and E' as w_E and $w_{E'}$, respectively. We denote the generalized Montgomery coefficients of these coordinates as α_{w_E} and $\alpha_{w_{E'}}$, respectively. Thus, if the halves of P are defined over $\mathbb{F}_p$, it holds that*

$$\alpha_{w_{E'}} = -2\frac{\alpha_{w_E}+6-12\sqrt{\alpha_{w_E}+2}}{\alpha_{w_E}+6+4\sqrt{\alpha_{w_E}+2}} = -2+\frac{32\sqrt{\alpha_{w_E}+2}}{(\sqrt{\alpha_{w_E}+2}+2)^2}, \tag{1}$$

and if the halves of P are in $\ker(\pi_p+1)$, the formula is obtained by replacing $\alpha_{w_{E'}}$ and α_{w_E} in Equation (1) with $-\alpha_{w_{E'}}$ and $-\alpha_{w_E}$, respectively, where π_p is the p-Frobenius map on E.

Theorem 12 (4-isogeny)**.** *Let $p \equiv 7 \pmod 8$, let E and E' be supersingular Montgomery$^-$ curves, and let $\phi\colon E \to E'$ be a 4-isogeny defined over $\mathbb{F}_p$ with $\ker\phi = \langle P\rangle$ defined over $\mathbb{F}_p$. We denote the w-coordinates on E and E' as w_E and $w_{E'}$, respectively. We denote the generalized Montgomery coefficients of these coordinates as α_{w_E} and $\alpha_{w_{E'}}$, respectively. Thus, if P is defined over $\mathbb{F}_p$, it holds that*

$$\frac{\alpha_{w_{E'}}+2}{4} = \frac{8\varepsilon\sqrt[4]{\frac{\alpha_{w_E}+2}{4}}\left(\sqrt{\frac{\alpha_{w_E}+2}{4}}+1\right)}{\left(2\sqrt[4]{\frac{\alpha_{w_E}+2}{4}}+\varepsilon\left(\sqrt{\frac{\alpha_{w_E}+2}{4}}+1\right)\right)^2}, \tag{2}$$

where $\varepsilon = (-1)^{\frac{p+1}{8}}$, and if P is in $\ker(\pi_p+1)$, the formula is obtained by replacing $\alpha_{w_{E'}}$ and α_{w_E} in Equation (2) with $-\alpha_{w_{E'}}$ and $-\alpha_{w_E}$, respectively.

To prove these theorems, we first prove the following lemmas.

Lemma 6. *Let $p \equiv 7 \pmod 8$, and let α be the generalized Montgomery coefficient of the w-coordinate of a supersingular Montgomery$^-$ curve defined over $\mathbb{F}_p$. Therefore, it holds that $\alpha+2 \in (\mathbb{F}_p)^2$ and $2-\alpha \in (\mathbb{F}_p)^2$.*

Proof. Let E be a Montgomery curve $y^2 = x^3+\alpha x^2+x$. From Remark 10, it holds that $\mathrm{End}_p(E) \cong \mathbb{Z}[\pi_p]$. Therefore, we obtain $E[8] \cap \ker(\pi_p-1) \cong \mathbb{Z}/8\mathbb{Z}$ and $E[8] \cap \ker(\pi_p+1) \cong \mathbb{Z}/8\mathbb{Z}$. Since $(1, \sqrt{\alpha+2}) \in E[4]$, $(1, \sqrt{\alpha+2})$ belongs to $2(\ker(\pi_p-1))$ or $2(\ker(\pi_p+1))$. From [36, Proposition 1], we have $(1, \sqrt{\alpha+2}) \in \ker(\pi_p-1)$. Therefore, $\alpha+2 \in (\mathbb{F}_p)^2$. Note that E has only one point of order 2 defined over $\mathbb{F}_p$. Hence, it holds that $\alpha^2-4 \notin (\mathbb{F}_p)^2$. Since $\alpha+2 \in (\mathbb{F}_p)^2$, it holds that $-(\alpha-2) \in (\mathbb{F}_p)^2$. □

Lemma 7. *Let $p \equiv 7 \pmod 8$, and let α be the generalized Montgomery coefficient of the w-coordinate of a supersingular Montgomery$^-$ curve defined over $\mathbb{F}_p$. If $p \equiv 15 \pmod{16}$, then $\sqrt{\alpha+2}+2 \in (\mathbb{F}_p)^2$ and $\sqrt{2-\alpha}+2 \in (\mathbb{F}_p)^2$, and if $p \equiv 7 \pmod{16}$, then $\sqrt{\alpha+2}+2 \notin (\mathbb{F}_p)^2$ and $\sqrt{2-\alpha}+2 \notin (\mathbb{F}_p)^2$.*

Proof. Since $-\alpha$ is also the generalized Montgomery coefficient of the w-coordinate of some supersingular Montgomery$^-$ curve, it is sufficient to consider whether $\sqrt{\alpha+2}+2$ is square. Let E be a Montgomery curve $y^2 = x^3 + \alpha x^2 + x$. Since E is on the floor, it holds that $E(\mathbb{F}_p)[8] \cong \mathbb{Z}/8\mathbb{Z}$. From Lemma 6, we obtain $(1, \sqrt{\alpha+2}) \in E(\mathbb{F}_p)[4]$. Therefore, the following equation has the roots in $\mathbb{F}_p$:

$$4(x^3 + \alpha x^2 + x) = (x^2-1)^2.$$

It is easy to observe that the roots of this equation are $-\frac{1}{2}(\sqrt[4]{\alpha+2} \pm \sqrt{\sqrt{\alpha+2}-2})^2$ and $\frac{1}{2}(\sqrt[4]{\alpha+2} \pm \sqrt{\sqrt{\alpha+2}+2})^2$. From Lemma 6, it holds that $\sqrt[4]{\alpha+2} \in \mathbb{F}_p$ and

$$(\sqrt{\alpha+2}-2)(\sqrt{\alpha+2}+2) = \alpha - 2 \notin (\mathbb{F}_p)^2.$$

Therefore, if $\sqrt{\alpha+2}+2$ is square in $\mathbb{F}_p$, then $\frac{1}{2}(\sqrt[4]{\alpha+2} \pm \sqrt{\sqrt{\alpha+2}+2})^2$ is a x-coordinate of a point of order 8 defined over $\mathbb{F}_p$, and if $\sqrt{\alpha+2}+2$ is not square in $\mathbb{F}_p$, then $-\frac{1}{2}(\sqrt[4]{\alpha+2} \pm \sqrt{\sqrt{\alpha+2}-2})^2$ is a x-coordinate of a point of order 8 defined over $\mathbb{F}_p$. We let P be a point of order 8 defined over $\mathbb{F}_p$. From [36, Proposition 1], if $\sqrt{\alpha+2}+2$ is square in $\mathbb{F}_p$, then $P \in 2E(\mathbb{F}_p)$. Hence, it holds that $16 \mid \#E(\mathbb{F}_p)$ and $p \equiv 15 \pmod{16}$. If $\sqrt{\alpha+2}+2$ is not square in $\mathbb{F}_p$, then $P \notin 2E(\mathbb{F}_p)$. Hence, it holds that $16 \nmid \#E(\mathbb{F}_p)$ and $p \equiv 7 \pmod{16}$. This completes the proof of Lemma 7. □

Now, we prove Theorems 11 and 12.

Theorem 11. From [7, Lemma 2 and Lemma 5], the halves of P are in $\ker(\pi_p - 1)$, or they are in $\ker(\pi_p + 1)$. We first consider a 4-isogeny from $F\colon y^2 = x^3 + \alpha_{w_E} x^2 + x$. From [25, equation (20)] and Lemma 6, it holds that

$$F_1 := F/\langle (1, \sqrt{\alpha_{w_E}+2}) \rangle\colon y^2 = x^3 - 2\frac{\alpha_{w_E}+6}{2-\alpha_{w_E}}x^2 + x,$$

$$F_2 := F/\langle (-1, \sqrt{(-1)(2-\alpha_{w_E})}) \rangle\colon y^2 = x^3 - 2\frac{\alpha_{w_E}-6}{\alpha_{w_E}+2}x^2 + x.$$

We denote one of the halves of P as Q. Let $\psi\colon E \to F$ be a 2-isogeny satisfying $w_E = x \circ \psi$. It is clear that if $Q \in \ker(\pi_p - 1)$ (*resp.* $Q \in \ker(\pi_p + 1)$), then $\psi(Q) \in \ker(\pi_p - 1)$ (*resp.* $\psi(Q) \in \ker(\pi_p + 1)$). Therefore, if $Q \in \ker(\pi_p - 1)$, then $Q = (1, \sqrt{\alpha_{w_E}+2})$, and if $Q \in \ker(\pi_p + 1)$, then $Q = (-1, \sqrt{\alpha_{w_E}-2})$. Hence, if $Q \in \ker(\pi_p - 1)$, then $E' \cong F_1$, and if $Q \in \ker(\pi_p + 1)$, then $E' \cong F_2$.

We now fix $Q \in \ker(\pi_p - 1)$. From Remark 10, it is sufficient to consider a 2-isogeny from F_1 to an elliptic curve on the floor. The points of order 2 are $(0,0)$ and

$$\left(\frac{\alpha_{w_E}+6 \pm 4\sqrt{\alpha_{w_E}+2}}{2-\alpha_{w_E}}, 0 \right).$$

Since $(0,0)$ is the backtrack point of the isogeny $F \to F_1$, the codomain of the isogeny whose kernel is $\langle (0,0) \rangle$ is on the surface. From [7, Lemma 2 and Lemma 5], the generator of the kernel of the isogeny mapping from F to an elliptic curve on the floor satisfies the x-coordinates of its halves are not in $\mathbb{F}_p$. Let

$$\tilde{\alpha}_\pm := \frac{\alpha_{w_E}+6 \pm 4\sqrt{\alpha_{w_E}+2}}{2-\alpha_{w_E}},$$

respectively. The x-coordinates of the halves of $(\tilde{\alpha}_\pm, 0)$ are the roots of the equation

$$\tilde{\alpha}_\pm = \frac{(x^2-1)^2}{4(x^3 - (\tilde{\alpha}_\pm + 1/\tilde{\alpha}_\pm)x^2 + x)}.$$

The roots of this equation is $x = \tilde{\alpha}_\pm \pm \sqrt{\tilde{\alpha}_\pm^2 - 1}$. Therefore, if $\tilde{\alpha}_\pm^2 - 1 \notin (\mathbb{F}_p)^2$, then $(\tilde{\alpha}_\pm, 0)$ is the generator of the kernel of the isogeny mapping from F to an elliptic curve on the floor. We have

$$\tilde{\alpha}_+^2 - 1 = \frac{8\sqrt{\alpha_{w_E}+2}}{(2-\alpha_{w_E})^2}(\sqrt{\alpha_{w_E}+2}+2)^2,$$

$$\tilde{\alpha}_-^2 - 1 = -\frac{8\sqrt{\alpha_{w_E}+2}}{(2-\alpha_{w_E})^2}(\sqrt{\alpha_{w_E}+2}-2)^2.$$

From Lemma 6, it holds that $\sqrt{\alpha_{w_E}+2}^{\frac{p-1}{2}} = (\alpha_{w_E}+2)^{\frac{p-1}{2}\frac{p+1}{4}} = 1$. Therefore, $\sqrt{\alpha_{w_E}+2} \in (\mathbb{F}_p)^2$. Since $p \equiv 7 \pmod 8$, we have $8 \in (\mathbb{F}_p)^2$. Therefore, $\tilde{\alpha}_+^2 - 1 \in (\mathbb{F}_p)^2$ and $\tilde{\alpha}_-^2 - 1 \notin (\mathbb{F}_p)^2$. Hence, the generator of the kernel of the target isogeny is $(\tilde{\alpha}_-, 0)$. Note that $\tilde{\alpha}_- = (\sqrt{\alpha_{w_E}+2}-2)^2/(2-\alpha_{w_E}) \in (\mathbb{F}_p)^2$. From [38, Proposition 2], we obtain $F_1/\langle(\tilde{\alpha}_-, 0)\rangle$ as

$$y^2 = x^3 - 2\frac{\alpha_{w_E}+6-12\sqrt{\alpha_{w_E}+2}}{\alpha_{w_E}+6+4\sqrt{\alpha_{w_E}+2}}x^2 + x.$$

Since $\alpha_{w_{E'}}$ is the Montgomery coefficient of this curve, we have completed the half of the proof.

If $Q \in \ker(\pi_p + 1)$, we have the following equation using the same discussion as above:

$$\alpha_{w_{E'}} = 2\frac{\alpha_{w_E}-6+12\sqrt{2-\alpha_{w_E}}}{\alpha_{w_E}-6-4\sqrt{2-\alpha_{w_E}}}.$$

This completes the proof of Theorem 11. □

Theorem 12. Since Montgomery$^-$ curves defined over $\mathbb{F}_p$ are on the surface [7, Figure 1 and Figure 2], the given 4-isogeny is the composition of 2-isogenies in Theorem 11. Lemma 7 provides the proof of Theorem 12. □

As [7, Figure 2] and Theorem 2 show, the generalized Montgomery coefficient of the w-coordinate is unique for an $\mathbb{F}_p$-isomorphism class. Subsequently, using the above theorems, we can construct a new CSURF algorithm via the w-coordinate of Montgomery$^-$ curves. In the previous CSURF algorithm, we had to move from the elliptic curves on the surface to those on the floor because of some speed-up techniques (*e.g.*, Radical isogenies [8, 37]). In contrast, because our proposed algorithm consists only of the arithmetic of curves on the floor, we can use these speed-up techniques without moving from one curve to another. Thus, this algorithm realizes a simple implementation using only one coordinate.

By this simplification, we can improve the efficiency of the algorithm of CSURF; however, unfortunately, the effect is likely be small.

7 CONCLUSION

In this paper, we proposed a novel function of elliptic curves called the generalized Montgomery coordinate. This is a generalization of some standard coordinates for one-coordinate arithmetics on elliptic curves that have been studied separately, *e.g.*, the x-coordinate of Montgomery curves, x-coordinate of Montgomery$^-$ curves, w-coordinate of Edwards curves, w-coordinate of Huff's curves, and ω-coordinates of twisted Jacobi intersections.

Next, we constructed explicit formulas of scalar multiplication including the division polynomial and isogeny computation via a generalized Montgomery coordinate. We obtained these formulas by considering the divisors of the functions related to scalar multiplication and isogeny computation. Note that our new formulas are independently constructed from the forms of elliptic curves that decide the above conventional coordinates. Moreover, two formulas are available for isogeny computation: one for an image point and the other for a target elliptic curve. The formula for an image point is unique for any generalized Montgomery coordinate; however, that for a target elliptic curve has some different forms. We proved that this difference is due to the division polynomial of the generalized Montgomery coordinates.

We believe the theory of a generalized Montgomery coordinate has many applications. In this paper, we considered two applications as an initial trial. First, we constructed a new formula for isogeny computation of Montgomery curves. This formula is based on that of w-coordinates on Edwards curves and is more efficient for large degree isogenies than previous formulas of Montgomery curves in our implementation. Furthermore, we proposed a new generalized Montgomery coordinate of Montgomery$^-$ curves. This coordinate enables us to construct the new CSURF algorithm that provides a simple implementation. An open problem remains to construct further applications of the generalized Montgomery coordinate.
