46

47 **ABSTRACT/SUMMARY**

48

49 **Background:** Glucagon-like peptide-1 (GLP-1) analogues reduce hepatic steatosis,
50 liver enzymes and insulin resistance in murine models of fatty liver disease. They are
51 licensed for type 2 diabetes, but their efficacy in patients with non-alcoholic
52 steatohepatitis is unknown. The aim of the study was to assess the efficacy and
53 safety of the long-acting GLP-1 analogue, liraglutide, in patients with non-alcoholic
54 steatohepatitis.

55

56 **Methods:** This multicentre, double-blinded, randomised, placebo-controlled phase II
57 trial was conducted in the UK to assess 48-weeks treatment with once-daily,
58 subcutaneous injections of 1.8mg liraglutide or liraglutide-placebo in overweight
59 patients with non-alcoholic steatohepatitis. Patients were randomly assigned 1:1
60 using a computer-generated, centrally administered procedure, stratified by trial
61 centre and diabetes status. The trial was designed using A'Herns single arm method
62 requiring 8/21 (38%) successes in the liraglutide arm. It incorporated a concurrently
63 randomised placebo group to provide an unbiased assessment of outcome for this
64 patient population. The primary outcome measure was improvement in liver
65 histology, defined as 'resolution of definite NASH' with no worsening in fibrosis from
66 baseline to end-of-treatment, as assessed centrally by two independent, blinded,
67 pathologists. Analysis was by intention-to-treat. The trial was registered with
68 ClinicalTrials.gov;NCT01237119.

69

70 **Findings:** Between 1st August 2010 and 31st May 2013, 26 patients were randomly

71 assigned to receive liraglutide and 26 to placebo. 45 (87%) of 52 patients underwent
72 end-of-treatment liver biopsy at 48 weeks. The primary end-point was met as 9/23
73 (39%) patients on liraglutide had resolution of definite NASH. This was higher than
74 the 2 (9%) of 22 responders on placebo (relative risk for all patients that had end-of-
75 treatment biopsy; 4.30, 95% CI 1.04 to 17.74; p=0.019). Fewer patients on liraglutide
76 (2/23; 9%) demonstrated progression of fibrosis compared to placebo (8/22; 36%)
77 (p=0.03).

78

79 **Interpretation:** Liraglutide was safe, well-tolerated and led to histological resolution
80 of non-alcoholic steatohepatitis, warranting extensive longer-term studies.

81

82 **Funding:** Wellcome Trust, National Institute of Health Research, Novo Nordisk Ltd.

83

84 **Key words:** Glucagon-like peptide 1, liraglutide, incretin mimetic, non-alcoholic fatty
85 liver, non-alcoholic steatohepatitis, liver biopsy

86

87 **Introduction**

88

89 Non-alcoholic steatohepatitis (NASH) is now the commonest cause of liver disease
90 and is predicted to be the main indication for liver transplantation by 2020.¹ Patients
91 with NASH have an increased risk of liver and cardiovascular disease (CVD) related
92 morbidity and mortality,² compared to those with non-alcoholic fatty liver (NAFL)
93 and the general population.^{3, 4} Moreover, there are currently no licensed therapies
94 for NASH.

95

96 Lifestyle modifications are the mainstay of treatment for NASH,⁵ yet most patients
97 fail to achieve, or maintain, dietary goals and weight loss.⁶ In the two largest
98 randomised controlled trials in patients with NASH thus far treatment with
99 pioglitazone, vitamin E (PIVENS)⁷ and obeticholic acid (FLINT)⁸ were associated with
100 improvements in liver histology compared to placebo, with the findings of the
101 PIVENS trial relevant to patients without type 2 diabetes. Concerns about the side-
102 effects and long-term safety profile of both pioglitazone and Vitamin E has reduced
103 enthusiasm for their use.⁹ Obeticholic acid also reduced liver fibrosis in the FLINT
104 trial and was associated with an elevated LDL cholesterol, which will be studied
105 further in phase 3.⁸

106

107 The strong association of NASH with the metabolic syndrome, in particular obesity
108 and type 2 diabetes, provides a compelling rationale for investigating therapies such
109 as the gut-derived incretin hormone, glucagon-like peptide-1 (GLP-1), that induce

110 weight loss and insulin sensitivity. Native GLP-1 has a potent blood glucose-lowering
111 action, mediated via its ability to induce insulin secretion and reduce glucagon
112 secretion in a glucose-dependent manner, as well as suppressing appetite and
113 delaying gastric emptying.¹⁰ Endogenous GLP-1 is degraded within minutes *in vivo* by
114 the enzyme dipeptidyl peptidase-4, whereas liraglutide is a long-acting (half-life 13
115 hours) human GLP-1 analogue.¹¹ Liraglutide has been shown to cause weight loss,¹²
116 decrease glycated haemoglobin (HbA1c) and systolic blood pressure and improve
117 beta-cell function,¹³ and is licensed for glycaemic control in patients with type 2
118 diabetes.

119

120 GLP-1 analogues have been shown to reduce liver enzymes and oxidative stress as
121 well as improving liver histology¹⁴ in murine models of NASH.¹⁵⁻¹⁷ This may reflect
122 their effects on obesity and systemic insulin resistance, although studies have also
123 reported that GLP-1 analogues can act directly on human hepatocytes *in vitro*, to
124 reduce steatosis by decreasing *de novo* lipogenesis and increasing fatty acid
125 oxidation.^{15, 18, 19}

126

127 To date, human studies investigating the effect of GLP-1 analogues on liver injury
128 have been limited to case reports,^{20, 21} a case series (n=8)²² and retrospective studies
129 of liver enzymes in patients with type 2 diabetes.^{23,24} However, these studies were
130 retrospective and lacked histological data, therefore we designed and conducted a
131 multi-centre randomised controlled trial of liraglutide to test its safety and efficacy in

132 the treatment of histologically confirmed NASH in overweight patients with and
133 without diabetes.

134

135

136

137

138

139 **Methods**

140

141 **Study Design:**

142 The Liraglutide Efficacy and Action in NASH (LEAN) trial was a multicentre, double-
143 blinded, randomised, placebo-controlled trial of 48 weeks treatment with the once
144 daily (OD) human GLP-1 analogue, liraglutide, in patients with biopsy-proven NASH.
145 Between 1st August 2010 and 31st May 2013, patients were recruited from 4 trial
146 centres at hospitals in the United Kingdom (UK). The National Research Ethics
147 Service (NRES) East Midlands–Northampton committee (UK) and the Medicines and
148 Healthcare products Regulatory Agency (MHRA) approved all versions of the study
149 protocol. In addition, all recruitment sites obtained approval from their local hospital
150 Research and Development (R&D) departments. The University of Birmingham
151 (Birmingham, UK) acted as the sponsor of the trial. A detailed version of the LEAN
152 protocol is published online.²⁵

153

154 **Participants:**

155 All patients provided written informed consent. The trial entry criteria were based
156 on a diagnosis of ‘definite’ NASH on liver biopsy obtained within 6 months of
157 screening. Prior to randomisation, two independent liver histopathologists (SGH, RB)
158 reviewed all of the liver biopsies to confirm whether a diagnosis of ‘definite’ NASH
159 was present, as defined by macrovesicular steatosis (>5%), hepatocyte ballooning
160 (with confirmation of the presence of Mallory’s Hyaline by ubiquitin
161 immunohistochemistry as necessary) and lobular inflammation (mixed infiltrate,

162 related to foci of ballooning).²⁶ In the event of disagreement with regards to a
163 diagnosis of 'definite' NASH, a combined assessment was undertaken to achieve
164 consensus. All participants had to be 18-70 years old and have a body mass index
165 (BMI) ≥ 25 kg/m² at screening. Patients with type 2 diabetes had to have stable
166 glycaemic control (HbA1c <9.0%) and be managed by either diet and/or a stable
167 dose of metformin/sulphonylurea.

168

169 Patients were excluded on the basis of: a history of significant alcohol consumption
170 (>20 g/day for women or >30 g/day for men), poor glycaemic control (HbA1c >
171 9.0%), Child-Pugh B/C cirrhosis, other causes of liver disease, confounding
172 concomitant medications (including insulin, incretin mimetics, thiazolidinediones,
173 vitamin E) and medical conditions including a history of pancreatitis and
174 pancreatic/thyroid carcinoma [Supplementary Methods].

175

176 **Randomisation and blinding:**

177 Patients who satisfied the eligibility criteria were randomly assigned (1:1) to 48
178 weeks treatment with subcutaneous injections of 1.8 mg liraglutide OD (Victoza®;
179 Novo Nordisk A/S, Denmark) or liraglutide-placebo (control; Novo Nordisk A/S,
180 Denmark) using a computer generated, centrally administered procedure at the
181 clinical trials unit (Birmingham). Randomisation was based on a minimisation
182 algorithm and stratified by trial site and diabetes status. To improve gastro-intestinal
183 tolerability patients underwent a 14-day dose titration, increasing their dose by 0.6
184 mg every 7 days from a starting dose of 0.6mg OD until the maximum dose of 1.8 mg

185 OD was achieved. Patients, investigators, clinical trial site staff and pathologists were
186 blinded to treatment assignment throughout the study.

187

188 **Procedures:**

189 After randomisation, patients returned for study visits at weeks 4, 12, 24, 36 and 48
190 (end of treatment), at which time the primary outcome was assessed. The end of
191 study was at week 60, 12 weeks after treatment finished. The schedule for the study
192 visits and data collection is summarised in the Appendix (Supplementary
193 methods/Table 1). All patients received standard National Health Services (NHS) care
194 recommendations on life-style modifications, including exercise, weight reduction
195 and dietary modification. Patients were not allowed any new prescriptions or over-
196 the-counter therapies that may impact on NASH throughout the duration of the
197 trial.²⁵ No dose reductions of liraglutide or placebo were allowed throughout the 48-
198 week treatment period. Previous treatment with oral anti-diabetic drugs (metformin
199 and/or sulphonylurea) was continued at the same dose in participants with type 2
200 diabetes at randomisation.

201

202 Two independent liver histopathologists (SGH, RB) assessed all baseline and end of
203 treatment liver biopsies to: (i) determine a diagnosis of 'definite NASH,' 'uncertain
204 NASH,' or 'not NASH', (ii) to assess the severity of liver disease including the NAFLD
205 activity score and fibrosis stage. The histopathologists were blinded to study
206 treatment allocation and clinical/laboratory information. Cases where there was

207 disagreement on the presence/absence of definite NASH were reviewed and
208 consensus reached. For each case consensus was reached for the fibrosis score.

209

210 **Outcomes:**

211 The primary outcome measure was assessed using an intention-to-treat analysis of
212 the proportion of evaluable patients achieving an improvement in liver histology
213 between liver biopsies at baseline and after 48 weeks of treatment. Histological
214 improvement was defined as a combination of the disappearance of steatohepatitis
215 (disappearance of hepatocyte ballooning) and no worsening in fibrosis (defined as an
216 increase by one stage of the Kleiner Fibrosis classification²⁷). Secondary histological
217 outcomes included changes in the overall NAS, individual components of NAS
218 (steatosis, hepatocyte ballooning, lobular inflammation) and the Kleiner fibrosis
219 stage.²⁷ Fibrosis stages 1a, 1b and 1c were considered as stage 1 for the purposes of
220 analysis. Other secondary outcome measures included changes from baseline to 48
221 weeks in serum liver enzymes, non-invasive hepatic biomarkers (CK-18, ELF test),
222 fasting lipids, glycaemic control (glucose, HbA1c), insulin resistance (HOMA-IR,
223 ADIPO-IR), anthropometric measures (body weight, BMI, waist circumference),
224 health-related quality of life scores (SF36v2 physical and mental components) and
225 dietary consumption per day.

226

227 **Statistical analysis**

228 The primary aim of the study was to assess whether the efficacy and safety profile of
229 liraglutide was worthy of further investigation. Recruiting patients into a no

230 treatment placebo-control group provided simultaneous unbiased assessment of
231 comparable patient groups. Based on other pharmaceutical trials in biopsy-proven
232 NASH, it was assumed that up to 20% of patients undergoing current standard of
233 care (placebo) would have an improvement in NASH by week 48. To justify further
234 investigation of liraglutide treatment, a clinically relevant improvement in liver
235 histology was considered to be 50% of patients. The sample size was calculated using
236 A'Hern's single stage phase II methodology, with a one-sided significance level of
237 0.05 (type 1 error) and power of 90% (type II error 0.10). The design required 21
238 evaluable patients in the treatment group. To account for withdrawal, the
239 recruitment target was inflated from 21 to 25 patients per treatment group.²⁵

240

241 All evaluable patients were analysed on an intention-to-treat basis. Evaluable
242 patients were defined as those who underwent an end-of-treatment biopsy (week
243 48). Patients were categorised as either achieving the primary histological outcome
244 (resolution of NASH) or not in each treatment group. The study A'Herns design
245 stipulated that 8 or more evaluable patients out of 21 (38%) in the liraglutide group
246 had to achieve histological improvement to be deemed worthy of further
247 investigation.²⁵

248

249 An unpowered pre-planned secondary analysis of the primary outcome measure was
250 performed using the chi-squared test to test for a difference between the
251 proportions of patients with histological improvement in each treatment group. In
252 addition, a sensitivity analysis was performed for the primary outcome measure, in

253 which patients that did not have an end-of-treatment liver biopsy were classified as
254 'no histological improvement' and included in the analysis. A *post hoc* logistic
255 regression analysis was undertaken to determine the treatment effect when
256 adjusted for the stratification variables of trial site and type 2 diabetes, stage of liver
257 fibrosis as well as weight and glycaemic change during the trial.

258

259 Adjusted relative risks were determined using the Mantel-Haenszel test for diabetes
260 and fibrosis. Continuous secondary outcome measures were compared between
261 treatment groups using linear regression, adjusting for parameter baseline values
262 and allocated treatment (as model covariates, equivalent to ANCOVA). Multilevel
263 modelling for key continuous outcome measures was undertaken to account for
264 repeated measures within each patient. Categorical secondary outcomes were
265 compared between treatment groups using chi-squared tests or Fisher's exact test
266 where appropriate. Statistical analyses were performed using Stata Statistical
267 Software: Release 12. College Station, TX: StataCorp LP.

268

269 Compliance with the trial protocol and safety profile of liraglutide was reviewed on
270 an annual basis by an independent DMC (appendix), and no concerns were raised.
271 The trial was registered with ClinicalTrials.gov (NCT01237119).

272

273 **Role of the funding source**

274 The LEAN trial represents independent academic research funded by the Wellcome
275 Trust, Novo Nordisk Ltd and the NIHR Birmingham Liver BRU. The funders of the

276 LEAN trial had no role in study design, data collection, data analysis, data
277 interpretation, or writing of the report. The corresponding author had access to all
278 data in the study and had final responsibility for the decision to submit for
279 publication.

280

281 **Results:**

282

283 52 patients with histologically confirmed 'definite' NASH on central pathology review
284 were randomly assigned to receive liraglutide (n=26) or placebo (n=26), between 1st
285 August 2010 and 31st May 2013 [Figure 1]. Participants were recruited from UK sites
286 as follows: Birmingham (n=31), Nottingham (n=12), Hull (n=6) and Leeds (n=3). With
287 the exception of one patient randomised to placebo, all patients received their
288 assigned treatment. Equal numbers of patients missed end of treatment (48-week)
289 biopsies (n=3) and withdrew from treatment (n=5) in each group. Baseline
290 demographic, clinical, laboratory and histological features were similar in the two
291 groups [Table 1]. Mean NAS was 4.9 (SD 0.9) and ranged from 3.0 to 6.5. Of 52
292 patients, stage 3 fibrosis was present in 21 (40%) and cirrhosis in 6 (12%) on central
293 review.

294

295 45 (87%) patients had paired (baseline, 48-week) liver biopsies, received treatment
296 and were included in the intention-to-treat analysis of the primary outcome. The
297 primary outcome (8 out of 21 successes (38%) for the single arm analysis) was met,
298 as 9 (39%) out of 23 patients in the liraglutide group had resolution of definite NASH
299 with no worsening of fibrosis [Table 2]. The alpha and power associated with 9 out of
300 23 successes under the same design conditions are 0.027 and 89.5% respectively.

301

302 2 (9%) out of 22 patients on placebo had histological improvement (relative risk 4.30,
303 95% CI 1.04 to 17.74; Chi-squared test of proportions (9/23 vs 2/22) p=0.019). A pre-

304 defined sensitivity analysis of the primary outcome measure, in which patients with
305 a missing end-of-treatment liver biopsy were defined as non-responders,
306 demonstrated that 9 out of 26 (35%) on liraglutide versus 2 out of 26 (7.7%) on
307 placebo achieved the primary outcome. This equated to patients on liraglutide
308 (versus placebo) having a relative risk of 4.5 (95% CI 1.1, 18.9; Chi-squared test,
309 $p=0.017$) of achieving the primary outcome. The odds ratio for the treatment effect
310 resulting from a logistic regression analysis adjusting for the stratification factors of
311 diabetes status and trial site is 7.83 (95%CI; 1.31, 46.68, $p=0.024$). No additional
312 analyses were performed to account for missing data as low absolute numbers of
313 dropout were observed.

314

315 Similar proportions of patients with [3 out of 8 [38%]] and without [6 out of 15
316 (40%)] type 2 diabetes achieved the primary outcome with liraglutide treatment.
317 Both patients assigned to placebo that achieved histological improvement did not
318 have type 2 diabetes at baseline. The relative risk for non-diabetic patients achieving
319 the primary end-point was 3.4 (95% CI 0.8, 14.4; $p=0.11$) for liraglutide versus
320 placebo. As there were no patients with diabetes that responded in the placebo arm
321 a factor of 0.5 was added to all 4 values in the contingency table for diabetic
322 patients. Using this adjustment the relative risk for diabetic patients was calculated
323 as 4.7 (95% CI 0.3, 75.0; $p=0.20$). There was no evidence of heterogeneity ($p=0.841$).
324 The relative risk of response on liraglutide compared to placebo adjusted for
325 diabetes using the stratified Mantel-Haenszel test was 3.7 (95% CI 1.0, 13.5;
326 $p=0.047$).

327

328 Fewer patients on liraglutide (2 of 23; 9%) demonstrated progression of fibrosis
329 compared to placebo (8 of 22; 36%); relative risk 0.2 (95% CI 0.1, 1.0); Fisher's exact
330 test, $p=0.04$). A greater proportion of patients on liraglutide had improvements in
331 steatosis (relative risk 1.8 (95% CI 1.1, 3.0); Chi-squared $p=0.01$) and hepatocyte
332 ballooning (relative risk 1.9 (95% CI 1.0, 3.8); Chi-squared $p=0.05$) compared to
333 placebo and no differences were seen in lobular inflammation (relative risk 0.9 (95%
334 CI 0.5, 1.6); Chi-squared $p=0.65$) and overall NAS (relative risk 1.2 (95% CI 0.8, 1.7);
335 Chi squared $p=0.46$) [Table 2].

336

337 Differences at 48 weeks in serum aminotransferases with liraglutide were not
338 significant compared to placebo, with only serum gamma-glutamyl transferase
339 reaching significance [Figure 2; Table 3]. However, multilevel modelling
340 (Supplementary Results) of longitudinal parameters indicated significant differences
341 in both alanine aminotransferase and gamma glutamyltransferase between the two
342 treatment arms thereby supporting the changes over time illustrated in Figure 2.
343 There were also trends in the reduction of serum biomarkers of hepatocyte injury
344 (serum CK-18; $p=0.097$) and fibrosis (serum ELF; $p=0.05$) with liraglutide compared to
345 placebo.

346

347 Compared with placebo, 48 weeks treatment with liraglutide was associated with
348 significant reductions in body weight and body mass index (Table 3). Most of the
349 beneficial effects of liraglutide on weight were achieved by 12 weeks treatment and

350 sustained throughout treatment [Figure 2]. Patients assigned to liraglutide also had
351 significant improvements in HbA1c compared to placebo. Improvements in weight
352 and HbA1c were confirmed by multilevel modelling (Supplementary Table 5).
353 Notably, weight increased and metabolic changes reverted towards baseline 12
354 weeks after liraglutide was discontinued [Figure 2; Supplementary Table 2]. There
355 was no significant difference in HDL or systolic blood pressure when assessed using
356 multilevel modelling.

357

358 *Post hoc* analysis was undertaken to determine the clinical/laboratory changes that
359 occurred in patients that had resolution of NASH with liraglutide treatment (n=9;
360 'responder') compared to those that did not (n=14; 'non-responder')
361 (Supplementary Table 7). Changes in weight and glycaemic control (HbA_{1c}) in
362 patients on liraglutide were not significantly different for responders and non-
363 responders (Figure 3a/b).

364

365 Patients on liraglutide reported significant improvements in the physical component
366 score of the SF36vs questionnaire compared to those on placebo (4.05 (95% CI; 0.20,
367 7.90; p=0.04).

368

369 The majority of AEs were grade 1 (mild) to grade 2 (moderate) in severity, transient
370 and similar in the two treatment groups for all organ classes and symptoms, with the
371 exception of gastrointestinal disorders (Table 4). Patients on liraglutide were prone
372 to diarrhoea (42% versus 19%), constipation (23% versus 0%) and loss of appetite

373 (31% versus 8%) compared to those on placebo. Patients with advanced fibrosis (F3-
374 4) had similar rates of AE to those with milder grades of fibrosis (Supplementary
375 Table 9). Two (8%) patients in the liraglutide group withdrew from treatment due to
376 nausea and diarrhoea, but still underwent liver biopsy at week 48. A further three
377 treatment withdrawals in the liraglutide group were due to needle phobia, work
378 commitments and loss to follow-up and withdrew their consent from the study and
379 did not undergo end-of-treatment liver biopsy.

380

381 There were two serious AEs in the liraglutide group (tuberculosis, migraines) both of
382 which were judged to be unrelated to therapy. There were no deaths nor cases of
383 pancreatitis, hepatitis or liver failure during the trial. No patients developed
384 antibodies against liraglutide on testing at week 60. *Post hoc* analysis highlighted
385 that the numbers of AEs were similar between patients with and without advanced
386 fibrosis (F3-F4) (Supplementary Table 9).

387

388

389

390

391

392 **Discussion**

393

394 In this double-blind, randomised, placebo-controlled phase II trial, the long-acting
395 GLP-1 analogue, liraglutide, met the pre-defined primary end-point and led to
396 resolution of NASH. Moreover, improvements in weight and glycaemic control with
397 liraglutide may have a favourable effect on the future risk of CVD and premature
398 death in patients with NASH, although longer term outcome studies are needed to
399 confirm this. Study withdrawal (i.e. no end-of-treatment biopsy) rates were the same
400 in both treatment groups and had no impact on the primary end-point. Liraglutide
401 was safe and well-tolerated, irrespective of the severity of underlying disease.

402

403 This study has a number of strengths. Firstly, this is the first randomised, placebo-
404 controlled trial to report the effect of a GLP-1 analogue on liver histology in patients
405 with NASH. Secondly, the study population included patients with and without type
406 2 diabetes and liver cirrhosis. Thirdly, in light of the documented intra- and inter
407 variability in assessment of liver biopsies²⁷ we had two independent, blinded, central
408 assessments of liver biopsies at baseline (same sections used for eligibility and
409 impact of treatment) and at end of treatment. This avoided inclusion of patients
410 without definite NASH, as happened in 21% and 20% of patients in PIVENS⁷ and
411 FLINT⁸ trials, respectively. Fourthly, we collated detailed recording of concomitant
412 medications (i.e. lipid-lowering and anti-diabetic medications) and dietary intake (i.e.
413 caffeine, vitamin E, alcohol) for the duration of the trial.

414

415 Our sample size was similar to previous proof-of concept studies ²⁸, albeit smaller

416 than some later stage phase 2 studies^{7,8}, and patients were extensively phenotyped
417 and well-matched for features of the metabolic syndrome with the exception of BMI.
418 The study was appropriately powered for a hard histological end-point, and the level
419 of histological resolution of NASH with liraglutide (9 of 23; 39%) was comparable to
420 that previously reported with vitamin E (29 of 80; 36%), pioglitazone (33 of 70; 47%)⁷
421 and obeticholic acid (22 of 102; 22%).⁸ The reported placebo rate (9%) was slightly
422 lower than those previously described (13-21%),^{7,8} but this is likely because in this
423 study clearance of NASH had to be accompanied without any worsening of fibrosis
424 (which has not been previously adopted).

425

426 Although liraglutide met the primary end-point, it did not result in significant mean
427 changes in the composite NAS score, as reported with pioglitazone, vitamin E and
428 obeticholic acid.^{7,8} Notably, a greater proportion of patients on liraglutide had
429 improvements in steatosis and hepatocyte ballooning indicating that the overall
430 pattern of changes are in keeping with a reduction in histological damage with
431 liraglutide. With the exception of lobular inflammation, a greater proportion of
432 patients on liraglutide improved steatosis (83% versus 45%; $p=0.009$) and hepatocyte
433 ballooning (61% versus 32%; $p=0.05$), which would suggest that a larger study could
434 identify significant mean changes in NAS. Liraglutide also showed evidence of
435 efficacy in a *post hoc* analysis using the primary end-points (which utilised NAS) that
436 were in place for the FLINT and PIVENS trials (Supplementary Table 6).

437

438 Resolution of NASH was selected as the primary end-point instead of changes in

439 NAS, in keeping with guidance from an expert consortium.²⁶ Notably, NAS score does
440 not predict liver-related morbidity or mortality, whereas the presence of NASH
441 (versus simple NAFL) is associated with a significant increase in liver-related
442 outcomes and all-cause mortality.^{3,4}

443

444 Recent data have identified the importance of liver fibrosis as being the key
445 determinant of clinical outcomes in patients with NASH.²⁹ Despite the relatively
446 short duration of this trial fewer patients on liraglutide had progression of fibrosis
447 ($p=0.04$) and there was also a greater reduction in serum ELF levels ($p=0.05$) than
448 placebo. Whilst there was no difference in mean change in fibrosis stage ($p=0.18$)
449 between the two groups this is likely a reflection of the duration of treatment, and a
450 longer course should be evaluated. Notably, the univariate analysis suggested that
451 patients with more severe fibrosis (F3/F4) at baseline were less likely to respond to
452 liraglutide, although liraglutide still had a positive treatment effect after adjusting for
453 baseline fibrosis (Supplementary Table 4).

454

455 The clearance of NASH by liraglutide is likely to be multi-factorial and a consequence
456 of its cumulative effect on weight loss and glycaemic control. Comparison of patients
457 with and without histological response to liraglutide, albeit limited by small
458 numbers, demonstrates a possible continued modest reduction in weight loss in
459 responders. *Post hoc* logistic regression (Supplementary Table 5) indicates that the
460 effects of liraglutide are likely to be due to a combination of a direct hepatic effect
461 (odds ratio for treatment effect adjusted for weight was 4.12 (CI 0.66-25.8; $p=0.131$))

462 and an effect on weight loss. This would imply that the mechanism of action of GLP-1
463 analogues in NASH is not solely explained by improvements in weight and metabolic
464 phenotype, and indeed *in vitro* studies have shown that GLP-1 analogues improve
465 the ability of the hepatocyte to handle excess NEFA and lipid production by
466 modulating lipid transport, beta-oxidation, and *de novo* lipogenesis,^{16, 18, 30} all of
467 which have been implicated in the pathogenesis of NASH. These observations have
468 been confirmed in liraglutide-treated mice, in which reductions in hepatic steatosis,
469 insulin resistance (via clamp technique) and endoplasmic reticulum oxidative stress
470 occurred in the absence of weight loss^{16, 31}. When this study was designed liraglutide
471 was only available at the 1.8mg dose, and since then a higher dose (3.0mg) has been
472 approved for weight management¹². It is possible that a higher dose of liraglutide
473 could provide greater efficacy in the setting of NASH, although the level of added
474 benefit is unclear.

475

476 Currently, safety data regarding the use of GLP-1 analogues in liver disease are
477 limited to solitary case reports^{20, 21} and retrospective analysis of large cohorts of
478 patients with type 2 diabetes and elevated transaminases.^{23, 24} Liraglutide was
479 generally well tolerated in the study and had a similar AE profile to placebo, with the
480 exception of predictable gastrointestinal symptoms (mainly diarrhoea, constipation
481 and loss of appetite). These, however, were mainly transient and mild-to-moderate
482 in severity.

483

484 At present, there is a significant unmet need of therapies in patients with NASH

485 cirrhosis. We, therefore, elected to include patients with cirrhosis in this study to
486 pilot the efficacy, but importantly highlight the safety of liraglutide in this setting.
487 Due to the fact that cirrhosis is the final stage of the Kleiner scoring system (e.g. 4/4),
488 these patients may have been advantaged in achieving the primary end-point, as by
489 definition they could not have 'worsening of fibrosis'. However, their inclusion did
490 not inflate the histological response in the liraglutide group, as only one patient with
491 cirrhosis met the primary end-point and they received placebo.

492

493 In conclusion, the unique combination of histological efficacy and improvement of
494 the metabolic syndrome with liraglutide render it an attractive therapy for patients
495 with NASH and warrant further investigation in larger studies.

496

497 **Panel: Research in context**

498 **Evidence before this study**

499 Non-alcoholic steatohepatitis (NASH) is now the commonest cause of chronic liver
500 disease and incurs a significantly increased risk of both liver- and cardiovascular
501 disease (CVD)-related morbidity and mortality.^{2, 4} Despite this, there are no licensed
502 therapies for NASH.⁵ To date, clinical trials of pioglitazone, vitamin E (PIVENS)⁷ and
503 obeticholic acid in patients with biopsy-proven NASH (FLINT)⁸ have shown
504 improvements in liver histology compared to placebo. With the exception of FLINT,
505 these trials have excluded patients with type 2 diabetes, thus their effects in patients
506 with diabetes are unknown. Moreover, there remain concerns about the side-effects
507 and long-term safety of pioglitazone and Vitamin E which has reduced enthusiasm
508 for their use.

509

510 In 2009, the long-acting glucagon-like peptide-1 (GLP-1) analogue, liraglutide, was
511 licensed for glycaemic control in overweight patients with type 2 diabetes.
512 Liraglutide also suppresses appetite centrally and delays gastric emptying¹⁰ which
513 induces weight loss^{12, 13} rendering it an attractive therapeutic option for NASH. Prior
514 to designing the LEAN trial, the published literature were reviewed by searching
515 PubMed, between 1st January 1965 and 31st December 2009, for ['NAFLD', 'NASH',
516 'fatty liver', 'steatohepatitis' or 'liver injury] and ['glucagon-like peptide 1', 'GLP-1',
517 'liraglutide', 'exenatide' or 'incretin']. GLP-1 analogues, including liraglutide,
518 improved liver enzymes, oxidative stress and hepatic steatosis in murine models *in*
519 *vivo* and in isolated *in vitro* murine and human hepatocyte studies.^{15, 16, 18, 19, 30, 31}

520 Human studies investigating the effect on liver injury were limited to single case
521 reports,^{20, 21} and large retrospective studies of liver enzymes in patients with type 2
522 diabetes.²³ An individual patient level meta-analysis of over 4000 patients with type
523 2 diabetes was performed, comparing 26 weeks of treatment with liraglutide to
524 placebo. Liraglutide significantly improved liver enzymes in a dose-dependent
525 manner, with comparable safety profiles in those patients with and without
526 abnormal liver biochemistry.²⁴ These findings formed the basis for this phase II
527 randomised, placebo-controlled trial of liraglutide for NASH. Despite extending the
528 literature search dates to 1st April 2015, no clinical trials of GLP-1 based therapies in
529 NASH were identified.

530

531 **Added value of this study**

532 This study is a first in class, randomised, controlled trial of GLP-1 analogue in patients
533 with NASH. Liraglutide met the primary end-point of histological resolution of NASH
534 with no worsening in fibrosis. In addition to improvements in histological steatosis
535 and hepatocyte ballooning, fewer patients on liraglutide had progression of fibrosis.
536 Uniquely for tested therapies in NASH, liraglutide improved several key components
537 of the metabolic syndrome, including weight and glycaemic control, which is
538 important, as cardiovascular disease accounts for the majority of deaths in cohorts
539 of patients with NASH.

540

541

542

543 **Implications of all the available evidence**

544 Due to the growing global burden of NASH and the lack of licensed therapies there is
545 a pressing need for effective interventions. Given the associated cardiovascular
546 morbidity and mortality with NASH, the use of therapies such as liraglutide which
547 improve both liver histology and many aspects of the metabolic syndrome are
548 needed to improve outcomes for patients with NASH. Future, longer-term studies
549 with liraglutide are needed to confirm their efficacy in patients with NASH, as well as
550 to establish their cardiovascular benefits.

551

552 **Contributors:**

553 MJA, SG, JWT and PNN (Chief Investigator) had the original concept of the LEAN trial.
554 MJA, DD, PG, DS, SG, JWT, RB, SGH and PNN designed the LEAN trial and
555 wrote/reviewed all protocol versions. RB and SGH carried out the central
556 histopathology review of all pre- and post-treatment liver biopsies. MJA and DB
557 (senior trials coordinator) submitted all REC, MHRA, local R&D applications and
558 coordinated the trial sites. PG (senior statistician) prepared the annual Data
559 Management Committee reports and performed all the statistical analysis. MJA,
560 GPA, GA, MAA, and PNN recruited the participants and MJA, GPA, DH, KG, DB, RP,
561 JMH, GA, MAA, RB, SGH and PNN were responsible for data collection. MJA, PG, RB,
562 SGH and PNN participated in data analysis and interpretation. MJA, PG and PNN
563 wrote the manuscript and all authors participated in manuscript review. MJA and PG
564 were responsible for preparation of the tables and figures. MJA, PG and PNN are
565 guarantors.

566 *Other members of the LEAN trial group that have been instrumental in the
567 conduct of the trial to date:

568 *Queen Elizabeth University Hospital Birmingham/NIHR Liver BRU/CRUKCTU*
569 *(Birmingham, UK):* Manpreet Wilku, Christine Russell, Salma Iqbal, Dr Christopher
570 Corbett, Michelle Yun Kyong Lee, Jennifer Keely and nursing staff at the WTCRF.

571 *Nottingham University Hospitals NHS Trust/ Nottingham Digestive Diseases BRU*
572 *(Nottingham, UK):* Maggie Nicholls and Susanne Henry.

574 *St James's University Hospital (Leeds, UK):* Samantha Sharman and Rebecca Bishop.

575

576 **Declaration of interests:**

577 PNN and MJA have received free trial drug supply from Novo Nordisk for conduct of
578 the LEAN trial of liraglutide in NASH. PNN has received an educational grant and
579 honoraria for lectures given on behalf of Novo Nordisk. SCG has served on advisory
580 boards for Novo Nordisk, Eli Lilly, Sanofi Aventis and Takeda, and has received
581 honoraria for lectures given on behalf of Novo Nordisk, Eli Lilly, Sanofi Aventis,
582 Takeda and GSK. PG, GPA, RP, DS, DH, KG, JMH, GA, MA, JWT, RB, SGH have no
583 conflict of interests to declare.

584

585

586 **Acknowledgements:**

587 The LEAN trial represents independent academic research funded by the Wellcome
588 Trust (clinical research training fellowship ref. 089780/Z/09/Z, awarded to MJA),

589 Novo Nordisk Ltd (educational grant awarded to PNN, free supply of trial drugs) and
590 the National Institute of Health Research (NIHR) Birmingham Liver Biomedical
591 Research Unit (BRU). The views expressed are those of the authors and not
592 necessarily those of the NHS, the NIHR or the Department of Health. The clinical
593 study was carried out at the NIHR/Wellcome Trust Birmingham Clinical Research
594 Facility. The LEAN trial team would like to express its gratitude to the patients
595 enrolled in the trial and the Data Management Committee (DMC) consisting of
596 Professor Peter Hayes (DMC Chair; independent Liver expert), Sarah Brown
597 (Independent Senior Statistician) and Dr Jude Oben (Independent Liver expert) for
598 their time and input.

599

600 **Figures legends:**

601 **Figure 1 Trial profile:** *One (1.9%) patient that was assigned to placebo never
602 received treatment, as they disclosed use of an ineligible medication (Dipeptidyl
603 peptidase-IV inhibitor) 24 hours post-randomisation.** Two patients randomised to
604 liraglutide withdrew from treatment (2, 16 weeks) due to adverse gastrointestinal
605 events, but still proceeded with the 48 week liver biopsy. One patient randomised to
606 placebo withdrew from treatment due to reactive hypoglycaemia (36 weeks) but still
607 proceeded with the 48 week liver biopsy.

608

609 **Figure 2. Changes from baseline in metabolic parameters and liver enzymes**
610 **according to treatment group.** Mean values (95% CI, error bars) of change from
611 baseline during treatment with liraglutide (*blue line*) or placebo (*red line*) for up to
612 48 weeks followed by a 12 week post-treatment period are shown (*broken line*). (A)
613 Weight, (B) HbA_{1c} and (D) Alanine aminotransferase decreased during treatment
614 with liraglutide with a rebound back toward baseline after discontinuation. (C)
615 Serum γ -glutamyl transpeptidase concentrations decreased with liraglutide
616 treatment. There was no difference in (E) HDL cholesterol and (F) systolic BP over
617 time between liraglutide and placebo.

618

619 **Figure 3. Changes from baseline in weight [a] and HbA_{1c} [b] for patients with and**
620 **without a histological response to liraglutide treatment.** Median values (IQR, error
621 bars) of changes from baseline in patients with histological improvement (responder;
622 *blue line*) and no histological improvement (non-responders; *red line*) on liraglutide

623 treatment for 48 weeks and post treatment follow-up (*broken line*) at 60 weeks.

624 Mean changes at 48 weeks and associated p-values are reported in Supplementary

625 Table 7.
