Abstract

We investigate the growth of the tallest peaks of random field solutions to the parabolic Anderson models over concentric balls as the radii approach infinity. The noise is white in time and correlated in space. The spatial correlation function is either bounded or non-negative satisfying Dalang's condition. The initial data are Borel measures with compact supports, in particular, include Dirac masses. The results obtained are related to those of Conus et al. (Ann Probab 41(3B):2225–2260, 2013) and Chen (Ann Probab 44(2):1535–1598, 2016) where constant initial data are considered.

1 Introduction

We consider the stochastic heat equation in \mathbb{R}^ℓ

$$\frac{\partial u}{\partial t} = \frac{1}{2} \Delta u + u \dot{W}, \quad u(0, \cdot) = u_0(\cdot) \quad (1.1)$$

where $t \geq 0$, $x \in \mathbb{R}^\ell$ ($\ell \geq 1$) and u_0 is a Borel measure. Herein, W is a centered Gaussian field, which is white in time and it has a correlated spatial covariance. More precisely, we assume that the noise W is described by a centered Gaussian family $W = \{W(\phi), \phi \in C_c^\infty(\mathbb{R}_+ \times \mathbb{R}^\ell)\}$, with covariance

$$\mathbb{E}[W(\phi)W(\psi)] = \frac{1}{(2\pi)^\ell} \int_0^\infty \int_{\mathbb{R}^\ell} \mathcal{F}\phi(s, \xi) \overline{\mathcal{F}\psi(s, \xi)} \mu(\xi) d\xi ds, \quad (1.2)$$

where μ is non-negative measurable function and \mathcal{F} denotes the Fourier transform in the spatial variables. To avoid trivial situations, we assume that μ is not identical to zero. The inverse Fourier transform of μ is in general a distribution defined formally by the expression

$$\gamma(x) = \frac{1}{(2\pi)^\ell} \int_{\mathbb{R}^\ell} e^{i\xi \cdot x} \mu(\xi) d\xi. \quad (1.3)$$

If γ is a locally integrable function, then it is non-negative definite and (1.2) can be written in Cartesian coordinates

$$\mathbb{E}[W(\phi)W(\psi)] = \int_0^\infty \iint_{\mathbb{R}^{2\ell}} \phi(s, x) \psi(s, y) \gamma(x - y) dx dy ds. \quad (1.4)$$

The following two distinct hypotheses on the spatial covariance of W are considered throughout the paper.

(H.1) μ is integrable, that is $\int_{\mathbb{R}^\ell} \mu(\xi) d\xi < \infty$. In this case, the inverse Fourier transform of $\mu(\xi)$ exists and is a bounded continuous function γ . Assume in addition that γ is κ -Hölder continuous function at 0.

(H.2) μ satisfies the following conditions:

(H.2a) The inverse Fourier transform of $\mu(\xi)$ is either the Dirac delta mass at 0 or a nonnegative locally integrable function γ .

(H.2b)

$$\int_{\mathbb{R}^\ell} \frac{\mu(\xi)}{1 + |\xi|^2} d\xi < \infty. \quad (1.5)$$

(H.2c) (Scaling) There exists $\alpha \in (0, 2)$ such that $\mu(c\xi) = c^{\alpha-\ell} \mu(\xi)$ for all positive numbers c .

Hereafter, we denote by $|\cdot|$ the Euclidean norm in \mathbb{R}^ℓ and by $x \cdot y$ the usual inner product between two vectors x, y in \mathbb{R}^ℓ . Condition (H.2b) is known as Dalang's condition and is sufficient for existence and uniqueness of a random field solution. If γ exists as a function, condition (H.2c) induces the scaling relation $\gamma(cx) = c^{-\alpha} \gamma(x)$ for all $c > 0$.

Equation (1.1) with noise satisfying condition (H.2) was introduced by Dalang in [9]. In [16], for a large class of initial data, we show that Eq. (1.1) has a unique random field solution under the hypothesis (H.2). Under hypothesis (H.1), we note that γ may be negative, but proceeding as in [18], a simple Picard iteration argument gives the existence and uniqueness of the solution. In addition, in both cases, the solution has finite moments of all positive orders. We give a few examples of covariance structures which are usually considered in literatures.

Example 1.1 Covariance functions satisfying (H.2) includes the Riesz kernel $\gamma(x) = |x|^{-\eta}$, with $0 < \eta < 2 \wedge \ell$, the space-time white noise in dimension one, where $\gamma = \delta_0$, the Dirac delta mass at 0, and the multidimensional fractional Brownian motion, where $\gamma(x) = \prod_{i=1}^{\ell} H_i(2H_i - 1)|x^i|^{2H_i-2}$, assuming $\sum_{i=1}^{\ell} H_i > \ell - 1$ and $H_i > \frac{1}{2}$ for $i = 1, \dots, \ell$. Covariance functions satisfying (H.1) includes $e^{-|x|^2}$ and the inverse Fourier transform of $|\xi|^2 e^{-|\xi|^2}$.

Suppose for the moment that \dot{W} is a space-time white noise and u_0 is a function satisfying

$$c \leq u_0(x) \leq C, \text{ for some positive numbers } c, C. \quad (1.6)$$

It is first noted in [7] that there exist positive constants c_1, c_2 such that almost surely

$$c_1 \leq \limsup_{R \rightarrow \infty} (\log R)^{-\frac{2}{3}} \log \sup_{|x| \leq R} u(t, x) \leq c_2. \quad (1.7)$$

Later Chen shows in [3] that indeed the precise almost sure limit can be computed, namely,

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{3}} \log \sup_{|x| \leq R} u(t, x) = \frac{3}{4} \left(\frac{2t}{3} \right)^{\frac{1}{3}} \text{ a.s.} \quad (1.8)$$

One of the key ingredients in showing (1.8) is the following moment asymptotic result

$$\lim_{m \rightarrow \infty} m^{-3} \log \mathbb{E} u(t, x)^m = \frac{t}{24}. \quad (1.9)$$

Thanks to the scaling property of the space-time white noise, Chen has managed to derive (1.9) from the following long term asymptotic result

$$\lim_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} u(t, x)^m = \mathcal{E}_m \quad (1.10)$$

where the constant \mathcal{E}_m grows as $\frac{1}{24}m^3$ when $m \rightarrow \infty$.

Under condition (1.6), analogous results for other kinds of noises are also obtained in [3]. More precisely, for noises satisfying (H.1)

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{1}{2}} \log \sup_{|x| \leq R} u(t, x) = \sqrt{2\ell\gamma(0)t} \text{ a.s.}, \quad (1.11)$$

and for noises satisfying (H.2),

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\alpha}} \sup_{|x| \leq R} \log u(t, x) = \frac{4-\alpha}{2} \ell^{\frac{2}{4-\alpha}} \left(\frac{\mathcal{E}_H(\gamma)}{2-\alpha} t \right)^{\frac{2-\alpha}{4-\alpha}} \quad \text{a.s.}, \quad (1.12)$$

where the variational quantity $\mathcal{E}_H(\gamma)$ is introduced in (3.3).

On the other hand, it is known that Eq. (1.1) has a unique random field solution under either (H.1) or (H.2) provided that u_0 satisfies

$$p_t * |u_0|(x) < \infty \quad \forall t > 0, x \in \mathbb{R}^\ell. \quad (1.13)$$

In the above and throughout the remaining of the article, $*$ denotes the convolution in spatial variables. Hence, condition (1.6) excludes other initial data of interests such as compactly supported measures. It is our purpose in the current paper to investigate the almost sure spatial asymptotic of the solutions corresponding to these initial data.

Upon reviewing the method in obtaining (1.8) described previously, one first seeks for an analogous result to (1.10) for general initial data. In fact, it is noted in [16] that for every u_0 satisfying (1.13), one has

$$\lim_{t \rightarrow \infty} \frac{1}{t} \log \sup_{x \in \mathbb{R}} \mathbb{E} \left(\frac{u(t, x)}{p_t * u_0(x)} \right)^m = \mathcal{E}_m, \quad (1.14)$$

where \mathcal{E}_m is a constant whose asymptotic as $m \rightarrow \infty$ is known. It is suggestive from (1.14) that with a general initial datum, one should normalized $u(t, x)$ in (1.8) (and (1.9)) by the factor $p_t * u_0(x)$. Therefore, we anticipate the following almost sure spatial asymptotic result.

Conjecture 1.2 Assume that u_0 satisfies (1.13). Under (H.1) we have

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{1}{2}} \sup_{|x| \leq R} (\log u(t, x) - \log p_t * u_0(x)) = \sqrt{2\ell\gamma(0)t} \quad \text{a.s.} \quad (1.15)$$

Under (H.2), we have

$$\begin{aligned} & \lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\alpha}} \sup_{|x| \leq R} (\log u(t, x) - \log p_t * u_0(x)) \\ &= \frac{4-\alpha}{2} \ell^{\frac{2}{4-\alpha}} \left(\frac{\mathcal{E}_H(\gamma)}{2-\alpha} t \right)^{\frac{2-\alpha}{4-\alpha}} \quad \text{a.s.} \end{aligned} \quad (1.16)$$

In the particular case of space-time white noise, we conjecture that

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{3}} \sup_{|x| \leq R} (\log u(t, x) - \log p_t * u_0(x)) = \frac{3}{4} \left(\frac{2t}{3} \right)^{\frac{1}{3}} \quad \text{a.s.} \quad (1.17)$$

In the case of space-time white noise, note that if u_0 satisfies the condition (1.6), (1.17) is no different than (1.8). On the other hand, if u_0 is a Dirac delta mass at x_0 , (1.17) precisely describes the spatial asymptotic of $\log u(t, x)$: at large spatial sites, $\log u(t, x)$ is concentrated near a logarithmic perturbation of the parabola $-\frac{1}{2t}(x - x_0)^2$. More precisely, (1.17) with this specific initial datum reduces to

$$\lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{3}} \sup_{|x| \leq R} \left(\log u(t, x) + \frac{(x - x_0)^2}{2t} \right) = \frac{3}{4} \left(\frac{2t}{3} \right)^{\frac{1}{3}}. \quad (1.18)$$

While a complete answer for Conjecture 1.2 (including (1.18)) is still undetermined, the current paper offers partial results, focusing on initial data with compact supports, especially Dirac masses. To unify the notation, we denote

$$\bar{\alpha} = \begin{cases} 0 & \text{if (H.1) holds,} \\ \alpha & \text{if (H.2) holds,} \end{cases} \quad \text{and} \quad \mathcal{E} = \begin{cases} \gamma(0) & \text{if (H.1) holds,} \\ \mathcal{E}_H(\gamma) & \text{if (H.2) holds,} \end{cases} \quad (1.19)$$

where the variational quantity $\mathcal{E}_H(\gamma)$ is introduced below in (3.3). For bounded covariance functions, we obtain the following result.

Theorem 1.3 *Assume that (H.1) holds and $u_0 = \delta(\cdot - x_0)$ for some $x_0 \in \mathbb{R}^\ell$. Then (1.15) holds.*

For noises satisfying (H.2), or for initial data with compact supports, the picture is less complete.

Theorem 1.4 *Assume that u_0 is a non-negative measure with compact support and either (H.1) or (H.2) holds. Then we have*

$$\begin{aligned} & \limsup_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\bar{\alpha}}} \sup_{|x| \leq R} (\log u(t, x) - \log p_t * u_0(x)) \\ & \leq \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{\mathcal{E}}{2 - \bar{\alpha}} t \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}} \quad \text{a.s.} \end{aligned} \quad (1.20)$$

For initial data satisfying (1.6), the lower bound of (1.16) is proved in [3] using a localization argument initiated from [7]. In our situation, a technical difficulty arises in applying this localization procedure, which leads to the missing lower bound in Theorem 1.4. A detailed explanation is given at the beginning of Sect. 6.2. As an attempt to obtain the exact spatial asymptotics, we propose an alternative result which is described below. We need to introduce a few more notation. For each $\varepsilon > 0$, we denote

$$\gamma_\varepsilon(x) = (2\pi)^{-\ell} \int_{\mathbb{R}^\ell} e^{-2\varepsilon|\xi|^2} e^{i\xi \cdot x} \mu(\xi) d\xi, \quad (1.21)$$

which is a bounded non-negative definite function. Let W_ε be a centered Gaussian field defined by

$$W_\varepsilon(\phi) = W(p_\varepsilon * \phi) \quad (1.22)$$

for all $\phi \in C_c^\infty(\mathbb{R}_+ \times \mathbb{R}^\ell)$. In the above, $p_\varepsilon = (2\pi\varepsilon)^{-\ell/2} e^{-|x|^2/(2\varepsilon)}$. The covariance structure of W_ε is given by

$$\begin{aligned} \mathbb{E}[W_\varepsilon(\phi)W_\varepsilon(\psi)] &= \frac{1}{(2\pi)^\ell} \int_0^\infty \int_{\mathbb{R}^\ell} \mathcal{F}\phi(s, \xi) \overline{\mathcal{F}\psi(s, \xi)} e^{-2\varepsilon|\xi|^2} \mu(\xi) d\xi ds \\ &= \int_0^\infty \iint_{\mathbb{R}^{2\ell}} \phi(s, x) \psi(s, y) \gamma_\varepsilon(x - y) dx dy ds \end{aligned} \quad (1.23)$$

for all $\phi, \psi \in C_c^\infty(\mathbb{R}_+ \times \mathbb{R}^\ell)$. In other words, W_ε is white in time and correlated in space with spatial covariance function γ_ε , which satisfies (H.1). Under condition (H.2c), γ_ε satisfies the scaling relation

$$\gamma_\varepsilon(x) = \varepsilon^{-\frac{\alpha}{2}} \gamma_1(\varepsilon^{-\frac{1}{2}}x) \quad \text{for all } \varepsilon > 0, x \in \mathbb{R}^\ell. \quad (1.24)$$

Let u_ε be the solution to Eq. (1.1) with \dot{W} replaced by \dot{W}_ε . It is expected that as $\varepsilon \downarrow 0$, $u_\varepsilon(t, x)$ converges to $u(t, x)$ in $L^2(\Omega)$ for each (t, x) , see [1] for a proof when the initial data is a bounded function. The following result describes spatial asymptotic of the family of random fields $\{u_\varepsilon\}_{\varepsilon \in (0, 1)}$.

Theorem 1.5 *Assume that u_0 is a non-negative measure with compact support and either (H.1) or (H.2) holds. Then*

$$\begin{aligned} \limsup_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\bar{\alpha}}} \sup_{|x| \leq R, \varepsilon \in (0, 1)} (\log u_\varepsilon(t, x) - \log p_t * u_0(x)) \\ \leq \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{\mathcal{E}}{2 - \bar{\alpha}} t \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}} \quad \text{a.s.} \end{aligned} \quad (1.25)$$

If, in particular, $u_0 = \delta(\cdot - x_0)$ for some $x_0 \in \mathbb{R}^\ell$, then

$$\begin{aligned} \lim_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\bar{\alpha}}} \sup_{|x| \leq R, \varepsilon \in (0, 1)} \left(\log u_\varepsilon(t, x) + \frac{(x - x_0)^2}{2t} \right) \\ = \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{\mathcal{E}}{2 - \bar{\alpha}} t \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}} \quad \text{a.s.} \end{aligned} \quad (1.26)$$

Neither one of (1.16) and (1.26) is stronger than the other. While the result of Theorem 1.5 relates to the solution of (1.1) indirectly, it is certainly interesting. In Hairer's theory of regularity structures (cf. [14]), one first regularizes the noise to obtain a sequence of approximated solutions. The solution of the corresponding stochastic partial differential equation is then constructed as the limiting object of this sequence. From this point of view, (1.26) provides a unified characteristic of the sequence of approximating solutions $\{u_\varepsilon\}_{\varepsilon \in (0, 1)}$, which approaches the solution u as $\varepsilon \downarrow 0$. The proof of (1.26) does not rely on localization, rather, on the Gaussian nature of the noise. This leads to a possibility of extending (1.26) to temporal colored noises, which will be a topic for future research.

The remainder of the article is structured as follows: In Sect. 2 we briefly summarize the theory of stochastic integrations and well-posedness results for (1.1). In Sect. 3 we introduce some variational quantities which are related to the spatial asymptotics. In Sect. 4 we derive some Feynman–Kac formulas of the solution and its moments, these formulas play a crucial role in our consideration. In Sect. 5 we investigate the high moment asymptotics and Hölder regularity of the solutions of (1.1) with respect to various parameters. The results in Sect. 5 are used to obtain upper bounds in (1.15) and (1.16). This is presented in Sect. 6, where we also give a proof of the lower bounds in Theorems 1.3, 1.4 and 1.5.

2 Preliminaries

We introduce some notation and concepts which are used throughout the article. The space of Schwartz functions is denoted by $\mathcal{S}(\mathbb{R}^\ell)$. The Fourier transform of a function $g \in \mathcal{S}(\mathbb{R}^\ell)$ is defined with the normalization

$$\mathcal{F}g(\xi) = \int_{\mathbb{R}^\ell} e^{-i\xi \cdot x} g(x) dx,$$

so that the inverse Fourier transform is given by $\mathcal{F}^{-1}g(\xi) = (2\pi)^{-\ell} \mathcal{F}g(-\xi)$. The Plancherel identity with this normalization reads

$$\int_{\mathbb{R}^\ell} |f(x)|^2 dx = \frac{1}{(2\pi)^\ell} \int_{\mathbb{R}^\ell} |\mathcal{F}f(\xi)|^2 d\xi.$$

Let us now describe stochastic integrations with respect to W . We can interpret W as a Brownian motion with values in an infinite dimensional Hilbert space. In this context, the stochastic integration theory with respect to W can be handled by classical theories (see for example, [11]). We briefly recall the main features of this theory.

We denote by \mathfrak{H}_0 the Hilbert space defined as the closure of $\mathcal{S}(\mathbb{R}^\ell)$ under the inner product

$$\langle g, h \rangle_{\mathfrak{H}_0} = \frac{1}{(2\pi)^\ell} \int_{\mathbb{R}^\ell} \mathcal{F}g(\xi) \overline{\mathcal{F}h(\xi)} \mu(\xi) d\xi. \quad (2.1)$$

which can also be written as

$$\langle g, h \rangle_{\mathfrak{H}_0} = \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} g(x) h(y) \gamma(x - y) dx dy. \quad (2.2)$$

If γ satisfies (H.1), then \mathfrak{H}_0 contains distributions such as Dirac delta masses. The Gaussian family W can be extended to an *isonormal Gaussian* process $\{W(\phi), \phi \in L^2(\mathbb{R}_+, \mathfrak{H}_0)\}$ parametrized by the Hilbert space $\mathfrak{H} := L^2(\mathbb{R}_+, \mathfrak{H}_0)$. For any $t \geq 0$, let \mathcal{F}_t be the σ -algebra generated by W up to time t . Let Λ be the space of \mathfrak{H}_0 -valued predictable processes g such that $\mathbb{E}\|g\|_{\mathfrak{H}}^2 < \infty$. Then, one can construct (cf. [16]) the

stochastic integral $\int_0^\infty \int_{\mathbb{R}^\ell} g(s, x) W(ds, dx)$ such that

$$\mathbb{E} \left(\int_0^\infty \int_{\mathbb{R}^\ell} g(s, x) W(ds, dx) \right)^2 = \mathbb{E} \|g\|_{\mathfrak{H}}^2. \quad (2.3)$$

To emphasize the variables, we sometimes write $\|g(s, y)\|_{\mathfrak{H}_{s,y}}$ for $\|g\|_{\mathfrak{H}}$. Stochastic integration over finite time interval can be defined easily

$$\int_0^t \int_{\mathbb{R}^\ell} g(s, x) W(ds, dx) = \int_0^\infty \int_{\mathbb{R}^\ell} 1_{[0,t]}(s) g(s, x) W(ds, dx).$$

Finally, the Burkholder's inequality in this context reads

$$\left\| \int_0^t \int_{\mathbb{R}^\ell} g(s, x) W(ds, dx) \right\|_{L^p(\Omega)} \leq \sqrt{4p} \left\| \int_0^t \|g(s, \cdot)\|_{\mathfrak{H}_0}^2 ds \right\|_{L^{\frac{p}{2}}(\Omega)}^{\frac{1}{2}}, \quad (2.4)$$

which holds for all $p \geq 2$ and $g \in \Lambda$. A useful application of (2.4) is the following result

Lemma 2.1 *Let $m \geq 2$ be an integer, f be a deterministic function on $[0, \infty) \times \mathbb{R}^\ell$ and $u = \{u(s, x) : s \geq 0, x \in \mathbb{R}^\ell\}$ be a predictable random field such that*

$$\mathcal{U}_m(s) := \sup_{x \in \mathbb{R}^\ell} \|u(s, x)\|_{L^m(\Omega)} < \infty.$$

Under hypothesis (H.2), we have

$$\left\| \int_0^t \int_{\mathbb{R}^\ell} f(s, y) u(s, y) W(ds, dy) \right\|_{L^m(\Omega)} \leq \sqrt{4m} \| |f(s, y)| \mathbf{1}_{[0,t]}(s) \mathcal{U}_m(s) \|_{\mathfrak{H}_{s,y}};$$

and under hypothesis (H.1), we have

$$\begin{aligned} & \left\| \int_0^t \int_{\mathbb{R}^\ell} f(s, y) u(s, y) W(ds, dy) \right\|_{L^m(\Omega)} \\ & \leq \sqrt{4m\gamma(0)} \left(\int_0^t \left(\int_{\mathbb{R}^\ell} f(s, y) dy \mathcal{U}_m(s) \right)^2 ds \right)^{\frac{1}{2}}. \end{aligned}$$

Proof We consider only the hypothesis (H.2), the other case is obtained similarly. In view of Burkholder inequality (2.4) and Minkowski inequality, it suffices to show

$$\int_0^t \| |f(s, \cdot)| u(s, \cdot) \|_{\mathfrak{H}_0}^2 \| \cdot \|_{L^{\frac{m}{2}}(\Omega)}^2 ds \leq \| |f(s, y)| \mathbf{1}_{[0,t]}(s) \mathcal{U}_m(s) \|_{\mathfrak{H}_{s,y}}^2. \quad (2.5)$$

In fact, using (2.2) and Minkowski inequality, the left-hand side in the above is at most

$$\int_0^t \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} |f(s, x)f(s, y)| \|u(s, x)u(s, y)\|_{L^{\frac{m}{2}}(\Omega)} \gamma(x - y) dx dy ds.$$

Note in addition that by Cauchy–Schwarz inequality,

$$\|u(s, x)u(s, y)\|_{L^{\frac{m}{2}}(\Omega)} \leq \|u(s, x)\|_{L^m(\Omega)}^{1/2} \|u(s, y)\|_{L^m(\Omega)}^{1/2} \leq \mathcal{U}_m(s).$$

From here, (2.5) is transparent and the proof is complete. \square

We now state the definition of the solution to Eq. (1.1) using the stochastic integral introduced previously.

Definition 2.2 Let $u = \{u(t, x), t \geq 0, x \in \mathbb{R}^\ell\}$ be a real-valued predictable stochastic process such that for all $t \geq 0$ and $x \in \mathbb{R}^\ell$ the process $\{p_{t-s}(x - y)u(s, y)\mathbf{1}_{[0,t]}(s), 0 \leq s \leq t, y \in \mathbb{R}^\ell\}$ is an element of Λ .

We say that u is a mild solution of (1.1) if for all $t \in [0, T]$ and $x \in \mathbb{R}^\ell$ we have

$$u(t, x) = p_t * u_0(x) + \int_0^t \int_{\mathbb{R}^\ell} p_{t-s}(x - y)u(s, y)W(ds, dy) \quad a.s. \quad (2.6)$$

The following existence and uniqueness result has been proved in [16] under hypothesis (H.2). Under hypothesis (H.1), one can proceed as in [18], using a simple Picard iteration argument to obtain the existence and uniqueness of the solution.

Theorem 2.3 Suppose that u_0 satisfies (1.13) and the spectral measure μ satisfies hypotheses (H.1) or (H.2). Then there exists a unique solution to Eq. (1.1).

When $u_0 = \delta(\cdot - z)$, we denote the corresponding unique solution by $\mathcal{Z}(z; t, x)$. In particular $\mathcal{Z}(z; \cdot, \cdot)$ is predictable and satisfies

$$\mathcal{Z}(z; t, x) = p_t(x - z) + \int_0^t \int_{\mathbb{R}^\ell} p_{t-s}(x - y)\mathcal{Z}(z; s, y)W(ds, dy) \quad (2.7)$$

for all $t \geq 0$ and $x \in \mathbb{R}^\ell$.

Next, we record a Gronwall-type lemma which will be useful later.

Lemma 2.4 Suppose $\alpha \in [0, 2)$ and f is a locally bounded function on $[0, \infty)$ such that

$$f_t \leq A \int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} f_s ds + B g_t \quad \text{for all } t \geq 0,$$

where A, B are positive constants and g is non-decreasing function. Then there exists a constant C_α such that

$$f_t \leq 2B g_t e^{C_\alpha A^{\frac{2}{2-\alpha}} t} \quad \text{for all } t \geq 0.$$

Proof Fix $T > 0$. For each $\rho > 0$, denote $D_\rho = \sup_{t \in [0, T]} f_t e^{-\rho t}$. It follows that

$$D_\rho \leq A \int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} e^{-\rho(t-s)} ds D_\rho + Bg_T.$$

It is easy to see

$$\begin{aligned} \int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} e^{-\rho(t-s)} ds &\leq 2 \int_{\frac{t}{2}}^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} e^{-\rho(t-s)} ds \\ &\leq 2^{1+\frac{\alpha}{2}} \int_0^\infty s^{-\frac{\alpha}{2}} e^{-\rho s} ds \\ &\leq C \rho^{-\frac{2-\alpha}{2}} \end{aligned}$$

for some suitable constant C depending only on α . We then choose $\rho = (2AC)^{\frac{2}{2-\alpha}}$ so that $AC\rho^{-\frac{2-\alpha}{2}} = \frac{1}{2}$. This leads to $D_\rho \leq 2Bg_T$, which implies the result. \square

Let us conclude this section by introducing a few key notation which we will use throughout the article. Let $B = (B(t), t \geq 0)$ denote a standard Brownian motion in \mathbb{R}^ℓ starting at the origin. For each $t > 0$, we denote

$$B_{0,t}(s) = B(s) - \frac{s}{t}B(t) \quad \forall s \in [0, t]. \quad (2.8)$$

The process $B_{0,t} = (B_{0,t}(s), 0 \leq s \leq t)$ is independent from $B(t)$ and is a Brownian bridge which starts and ends at the origin. An important connection between B and $B_{0,t}$ is the following identity. For every $\lambda \in (0, 1)$ and every bounded measurable function F on $C([0, \lambda t]; \mathbb{R}^d)$ we have

$$\begin{aligned} &\mathbb{E}[F(\{B_{0,t}(s); 0 \leq s \leq \lambda t\})] \\ &= (1-\lambda)^{-\frac{d}{2}} \mathbb{E}\left[\exp\left\{-\frac{|B(\lambda t)|^2}{2(1-\lambda)t}\right\} F(\{B(s); 0 \leq s \leq \lambda t\})\right]. \end{aligned} \quad (2.9)$$

This is in fact an application of Girsanov's theorem, see [16, Eq. (2.8)] for more details.

Let B^1, B^2, \dots be independent copies of B and $B_{0,t}^1, B_{0,t}^2, \dots$ be the corresponding Brownian bridges. An important quantity which appears frequently in our consideration is

$$\Theta_t(m) := \sup_{s \in (0, t]} \mathbb{E} \exp \left\{ \int_0^s \sum_{1 \leq j < k \leq m} \gamma(B_{0,s}^j(r) - B_{0,s}^k(r)) dr \right\}. \quad (2.10)$$

From the proof of Proposition 4.2 in [16], it is easy to see that under one of the hypotheses (H.1) and (H.2), $\Theta_t(m) < \infty$ for any $t > 0$. Finally, $A \lesssim E$ means $A \leq CE$ for some positive constant C , independent from all the terms appearing in E .

3 Variations

We introduce two variational quantities and give their basic properties and relations. The high moment asymptotic is governed by a variational quantity which is known as the Hartree energy (cf. [8]). If there exists a locally integrable function γ whose Fourier transform is μ , then the Hartree energy can be expressed as

$$\mathcal{E}_H(\gamma) = \sup_{g \in \mathcal{G}} \left\{ \int_{\mathbb{R}^\ell} \int_{\mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy - \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right\}, \quad (3.1)$$

where \mathcal{G} is the set

$$\mathcal{G} = \left\{ g \in W^{1,2}(\mathbb{R}^\ell) : \|g\|_{L^2(\mathbb{R}^\ell)} = 1 \right\}. \quad (3.2)$$

The subscript H stands for “Hartree”. We can also write this variation in Fourier mode. Indeed, the presentation (1.3) leads to

$$\begin{aligned} \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy &= (2\pi)^{-\ell} \int_{\mathbb{R}^\ell} |\mathcal{F}[g^2](\xi)|^2 \mu(\xi) d\xi \\ &= (2\pi)^{-3\ell} \int_{\mathbb{R}^\ell} |\mathcal{F}g * \mathcal{F}g(\xi)|^2 \mu(\xi) d\xi. \end{aligned}$$

Setting $h = (2\pi)^{-\frac{\ell}{2}} \mathcal{F}g$ so that $\|h\|_{L^2} = 1$, we arrive at

$$\mathcal{E}_H(\gamma) = \sup_{h \in \mathcal{A}} \left\{ (2\pi)^{-\ell} \int_{\mathbb{R}^\ell} |h * h(\xi)|^2 \mu(\xi) d\xi - \int_{\mathbb{R}^\ell} |h(\xi)|^2 |\xi|^2 d\xi \right\} \quad (3.3)$$

where

$$\mathcal{A} = \left\{ h : \mathbb{R}^\ell \rightarrow \mathbb{C} \mid \|h\|_{L^2(\mathbb{R}^\ell)} = 1, \int_{\mathbb{R}^\ell} |\xi|^2 |h(\xi)|^2 d\xi < \infty \text{ and } \overline{h(\xi)} = h(-\xi) \right\}.$$

Under (H.1), from (3.1), we bound $\gamma(x-y)$ from above by $\gamma(0)$, it follows that $\mathcal{E}_H(\gamma) \leq \gamma(0)$, which is finite. The fact that this variation (either in the form (3.1) or (3.3)) is finite under the condition (H.2) is not immediate. In some special cases, this is verified in [6] and [5].

Proposition 3.1 *Suppose (1.5) holds. Then $\mathcal{E}_H(\gamma)$ is finite.*

Proof Our proof is based on the argument in [5, Proposition 3.1]. Here, however, we work on the frequency space and use the presentation (3.3). Let h be in \mathcal{A} . Applying Cauchy–Schwarz inequality yields

$$|h * h(\xi)|^2 = \left| \int_{\mathbb{R}^\ell} h(\xi - \xi') h(\xi') d\xi' \right|^2 \leq \int_{\mathbb{R}^\ell} |h(\xi - \xi')|^2 d\xi' \int_{\mathbb{R}^\ell} |h(\xi')|^2 d\xi' = 1.$$

On the other hand, using the elementary inequality

$$|\xi|^2 \leq 2|\xi - \xi'|^2 + 2|\xi'|^2$$

and Cauchy–Schwarz inequality, we also get

$$\begin{aligned} |\xi|^2 |h * h(\xi)|^2 &\leq 2 \left| \int_{\mathbb{R}^\ell} h(\xi - \xi') |\xi - \xi'| h(\xi') d\xi' \right|^2 + 2 \left| \int_{\mathbb{R}^\ell} h(\xi - \xi') |\xi'| h(\xi') d\xi' \right|^2 \\ &\leq 4 \int_{\mathbb{R}^\ell} |h(\xi')|^2 |\xi'|^2 d\xi'. \end{aligned}$$

Then, for every $R > 0$ we have

$$\begin{aligned} \int_{\mathbb{R}^\ell} |h * h(\xi)|^2 \mu(\xi) d\xi &= \int_{|\xi| \leq R} |h * h(\xi)|^2 \mu(\xi) d\xi + \int_{|\xi| > R} |h * h(\xi)|^2 \mu(\xi) d\xi \\ &\leq \int_{|\xi| \leq R} \mu(\xi) d\xi + 4 \int_{|\xi| > R} \frac{\mu(\xi)}{|\xi|^2} d\xi \int_{\mathbb{R}^\ell} |h(\xi')|^2 |\xi'|^2 d\xi'. \end{aligned}$$

We now choose R sufficiently large so that $4(2\pi)^{-\ell} \int_{|\xi| > R} \frac{\mu(\xi)}{|\xi|^2} d\xi < 1$. This implies

$$(2\pi)^{-\ell} \int_{\mathbb{R}^\ell} |h * h(\xi)|^2 \mu(\xi) d\xi - \int_{\mathbb{R}^\ell} |h(\xi)|^2 |\xi|^2 d\xi \leq (2\pi)^{-\ell} \int_{|\xi| \leq R} \mu(\xi) d\xi$$

for all h in \mathcal{A} , which finishes the proof. \square

In establishing the lower bound of spatial asymptotic, another variation arises, which is given by

$$\mathcal{M}(\gamma) = \sup_{g \in \mathcal{G}} \left\{ \left(\int_{\mathbb{R}^\ell} \int_{\mathbb{R}^\ell} \gamma(x - y) g^2(x) g^2(y) dx dy \right)^{\frac{1}{2}} - \frac{1}{2} \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right\}, \quad (3.4)$$

or alternatively in frequency mode

$$\mathcal{M}(\gamma) = \sup_{h \in \mathcal{A}} \left\{ \left((2\pi)^{-\ell} \int_{\mathbb{R}^\ell} |h * h(\xi)|^2 \mu(\xi) d\xi \right)^{\frac{1}{2}} - \frac{1}{2} \int_{\mathbb{R}^\ell} |h(\xi)|^2 |\xi|^2 d\xi \right\}. \quad (3.5)$$

Lemma 3.2 $\lim_{\varepsilon \rightarrow 0} \mathcal{E}_H(\gamma_\varepsilon) = \mathcal{E}_H(\gamma)$ and $\lim_{\varepsilon \rightarrow 0} \mathcal{M}(\gamma_\varepsilon) = \mathcal{M}(\gamma)$, where we recall that γ_ε is defined in (1.21).

Proof We only prove the first limit, the second limit is proved analogously. Let g be in \mathcal{G} . Note that

$$\liminf_{\varepsilon \downarrow 0} \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma_\varepsilon(x - y) g^2(x) g^2(y) dx dy$$

$$\begin{aligned}
 &= \liminf_{\varepsilon \downarrow 0} (2\pi)^{-3\ell} \int_{\mathbb{R}^\ell} |\mathcal{F}g * \mathcal{F}g(\xi)|^2 e^{-2\varepsilon|\xi|^2} \mu(\xi) d\xi \\
 &\geq (2\pi)^{-3\ell} \int_{\mathbb{R}^\ell} |\mathcal{F}g * \mathcal{F}g(\xi)|^2 \mu(\xi) d\xi = \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy
 \end{aligned}$$

by Fatou's lemma. Since $\mathcal{E}_H(\gamma_\varepsilon)$ is finite, we have

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma_\varepsilon(x-y) g^2(x) g^2(y) dx dy - \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \leq \mathcal{E}_H(\gamma_\varepsilon).$$

Sending ε to 0 yields

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy - \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \leq \liminf_{\varepsilon \downarrow 0} \mathcal{E}_H(\gamma_\varepsilon).$$

Since the above inequality holds for every g in \mathcal{G} , we obtain $\mathcal{E}_H(\gamma) \leq \liminf_{\varepsilon \downarrow 0} \mathcal{E}_H(\gamma_\varepsilon)$. On the other hand, it is evident (from (3.3)) that $\mathcal{E}_H(\gamma_\varepsilon) \leq \mathcal{E}_H(\gamma)$. This concludes the proof. \square

Under the scaling condition (H.2c), \mathcal{E}_H and \mathcal{M} are linked together by the following result.

Proposition 3.3 *Assuming condition (H.2c), $\mathcal{E}_H(\gamma)$ is finite if and only if $\mathcal{M}(\gamma)$ is finite. In addition,*

$$\mathcal{M}(\gamma) = \frac{4-\alpha}{4} \left(\frac{2\mathcal{E}_H(\gamma)}{2-\alpha} \right)^{\frac{2-\alpha}{4-\alpha}}.$$

Before giving the proof, let us see how (3.1) and (3.4) are connected to a certain interpolation inequality. Under scaling condition (H.2c), it is a routine procedure in analysis to connect the finiteness of $\mathcal{E}_H(\gamma)$ with a certain interpolation inequality. For instance, when $\gamma = \delta$ and $\ell = 1$, the fact that

$$\sup_{g \in \mathcal{G}} \left\{ \int_{\mathbb{R}} g^4(x) dx - \int_{\mathbb{R}} |g'(x)|^2 dx \right\} < \infty$$

is equivalent to the following Gagliardo–Nirenberg inequality

$$\|g\|_{L^4} \leq C \|g\|_{L^2}^{3/4} \|g'\|_{L^2}^{1/4}$$

for all g in $W^{1,2}(\mathbb{R})$. For readers' convenience, we provide a brief explanation below.

Proposition 3.4 *Assume that the scaling relation (H.2c) holds.*

(i) *If $\mathcal{E}_H(\gamma)$ is finite then there exists $\kappa > 0$ such that for all g in $W^{1,2}(\mathbb{R}^\ell)$*

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy \leq \kappa \left(\int_{\mathbb{R}^\ell} |g(x)|^2 dx \right)^{2-\frac{\alpha}{2}} \left(\int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right)^{\frac{\alpha}{2}}. \quad (3.6)$$

In addition the constant κ can be chosen to be $\kappa(\gamma)$ where

$$\kappa(\gamma) := \frac{2}{\alpha} \left(\frac{\alpha}{2-\alpha} \mathcal{E}_H(\gamma) \right)^{\frac{2-\alpha}{2}}. \quad (3.7)$$

(ii) If (3.6) holds for some finite constant $\kappa > 0$, then $\mathcal{E}_H(\gamma)$ is finite and the best constant in (3.6) is $\kappa(\gamma)$.

Proof Recall that \mathcal{G} is defined in (3.2).

(i) Let g be in \mathcal{G} . For each $\theta > 0$, the function $x \mapsto g_\theta(x) := \theta^{\frac{\ell}{2}} g(\theta x)$ also belongs to \mathcal{G} . Hence,

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g_\theta^2(x) g_\theta^2(y) dx dy - \int_{\mathbb{R}^\ell} |\nabla g_\theta(x)|^2 dx \leq \mathcal{E}_H(\gamma).$$

Writing these integrals back to g and using (H.2c) yields

$$\theta^\alpha \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy - \theta^2 \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \leq \mathcal{E}_H(\gamma)$$

for all $\theta > 0$. Optimizing the left-hand side (with respect to θ) leads to

$$\begin{aligned} & \frac{2-\alpha}{\alpha} \left(\frac{\alpha}{2} \right)^{\frac{2}{2-\alpha}} \left(\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy \right)^{\frac{2}{2-\alpha}} \\ & \leq \mathcal{E}_H(\gamma) \left(\int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right)^{\frac{\alpha}{2-\alpha}}. \end{aligned}$$

Removing the normalization $\|g\|_{L^2} = 1$ and some algebraic manipulation yields the result.

(ii) Let κ_0 be the best constant in (3.6). Then for every $g \in \mathcal{G}$,

$$\begin{aligned} & \iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} \gamma(x-y) g^2(x) g^2(y) dx dy - \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \leq \kappa_0 \|\nabla g\|_{L^2}^\alpha - \|\nabla g\|_{L^2}^2 \\ & \leq \sup_{\theta > 0} \{\kappa_0 \theta^\alpha - \theta^2\} = \frac{2-\alpha}{\alpha} \left(\frac{\alpha}{2} \kappa_0 \right)^{\frac{2}{2-\alpha}}. \end{aligned}$$

This shows $\mathcal{E}_H(\gamma)$ is finite and at most $\frac{2-\alpha}{\alpha} \left(\frac{\alpha}{2} \kappa_0 \right)^{\frac{2}{2-\alpha}}$, which also means $\kappa(\gamma) \leq \kappa_0$. On the other hand, (i) already implies $\kappa_0 \leq \kappa(\gamma)$, hence completes the proof. \square

Proof of Proposition 3.3 Reasoning as in Proposition 3.4, we see that $\mathcal{M}(\gamma)$ is finite if and only if (3.6) holds for some constant $\kappa > 0$. In addition, the best constant $\kappa(\gamma)$ in (3.6) satisfies the relation

$$\mathcal{M}(\gamma) = \frac{4-\alpha}{4} \left(\frac{\alpha}{2} \right)^{\frac{\alpha}{4-\alpha}} (\kappa(\gamma))^{\frac{2}{4-\alpha}}.$$

Together with (3.7), this yields the result. \square

The following result preludes the connection between $\mathcal{E}_H, \mathcal{M}$ with exponential functional of Brownian motions.

Lemma 3.5 *Let $\{B(s), s \geq 0\}$ be a Brownian motion in \mathbb{R}^n and D be a bounded open domain in \mathbb{R}^n containing 0. Let $h(s, x)$ be a bounded function defined on $[0, 1] \times \mathbb{R}^n$ which is continuous in x and equicontinuous (over $x \in \mathbb{R}^n$) in s . Then*

$$\begin{aligned} & \lim_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} \left[\exp \left\{ \int_0^t h \left(\frac{s}{t}, B(s) - \frac{s}{t} B(t) \right) ds \right\}; \tau_D \geq t \right] \\ &= \int_0^1 \sup_{g \in \mathcal{G}_D} \left\{ \int_D h(s, x) g^2(x) dx - \frac{1}{2} \int_D |\nabla g(x)|^2 dx \right\} ds, \end{aligned} \quad (3.8)$$

where \mathcal{G}_D is the class of functions g in $W^{1,2}(\mathbb{R}^n)$ such that $\int_D |g(x)|^2 dx = 1$ and τ_D is the exit time $\tau_D := \inf\{t \geq 0 : B_t \notin D\}$.

Proof Observe that the process $\{B_{0,t}(s) = B(s) - \frac{s}{t} B(t)\}_{s \in [0,t]}$ is a Brownian bridge. An analogous result with Brownian bridge replaced by Brownian motion has been obtained in [6]. Our main idea here is to apply a change of measure to transfer the known result for Brownian motion to the result for Brownian bridge (i.e. the limit (3.8)). Since the probability density of Brownian bridge $B_{0,t}$ with respect to a standard Brownian motion is singular near t , a truncation is needed. We fix $\theta \in (0, 1)$ and consider first the limit

$$\lim_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\}; \tau_D \geq t \right].$$

Let M be such that $|x| \leq M$ for all $x \in D$. Using Girsanov theorem (see [16, Eq. (2.38)]), we can write

$$\begin{aligned} & \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\}; \tau_D \geq t \right] \\ &= (1 - \theta)^{-\frac{n}{2}} \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B(s) \right) ds - \frac{|B(\theta t)|^2}{2t(1 - \theta)} \right\}; \tau_D \geq t \right] \\ &\geq (1 - \theta)^{-\frac{n}{2}} \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B(s) \right) ds - \frac{M^2}{2t(1 - \theta)} \right\}; \tau_D \geq t \right]. \end{aligned} \quad (3.9)$$

The result of [6, Proposition 3.1] asserts that

$$\begin{aligned} & \lim_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B(s) \right) ds \right\}; \tau_D \geq t \right] \\ &= \int_0^\theta \sup_{g \in \mathcal{G}_D} \left\{ \int_D h(s, x) g^2(x) dx - \frac{1}{2} \int_D |\nabla g(x)|^2 dx \right\} ds. \end{aligned} \quad (3.10)$$

This leads to

$$\begin{aligned} & \liminf_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\}; \tau_D \geq t \right] \\ & \geq \int_0^\theta \sup_{g \in \mathcal{G}_D} \left\{ \int_D h(s, x) g^2(x) dx - \frac{1}{2} \int_D |\nabla g(x)|^2 dx \right\} ds. \end{aligned} \quad (3.11)$$

In obtaining the above limit, we have used the trivial facts

$$\lim_{t \rightarrow \infty} \frac{1}{t} \log(1 - \theta)^{-\frac{n}{2}} = \lim_{t \rightarrow \infty} \frac{1}{t} \log \exp \left\{ -\frac{M^2}{2t(1 - \theta)} \right\} = 0.$$

Note that the singularity when $\theta \uparrow 1$ has disappeared at this stage. On the other hand, the estimate

$$\left| \log \mathbb{E} \exp \left\{ \int_0^t h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\} - \log \mathbb{E} \exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\} \right| \leq (1 - \theta)t \|h\|_\infty$$

implies that

$$\begin{aligned} & \lim_{\theta \uparrow 1} \limsup_{t \rightarrow \infty} \left| \frac{1}{t} \log \mathbb{E} \exp \left\{ \int_0^t h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\} \right. \\ & \quad \left. - \frac{1}{t} \log \mathbb{E} \exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\} \right| = 0. \end{aligned}$$

Hence, we can send $\theta \uparrow 1$ in (3.11) to obtain the lower bound for (3.8). The upper bound for (3.8) is proved analogously. Indeed, from (3.9), we have

$$\begin{aligned} & \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\}; \tau_D \geq t \right] \\ & \leq (1 - \theta)^{-\frac{n}{2}} \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B(s) \right) ds + \frac{M^2}{2t(1 - \theta)} \right\}; \tau_D \geq t \right], \end{aligned}$$

which when combined with (3.10) yields

$$\begin{aligned} & \limsup_{t \rightarrow \infty} \frac{1}{t} \log \mathbb{E} \left[\exp \left\{ \int_0^{\theta t} h \left(\frac{s}{t}, B_{0,t}(s) \right) ds \right\}; \tau_D \geq t \right] \\ & \leq \int_0^\theta \sup_{g \in \mathcal{G}_D} \left\{ \int_D h(s, x) g^2(x) dx - \frac{1}{2} \int_D |\nabla g(x)|^2 dx \right\} ds. \end{aligned}$$

Since the singularity when $\theta \uparrow 1$ has been eliminated in the regime $t \rightarrow \infty$, we can send $\theta \uparrow 1$ as previously to obtain the upper bound for (3.8). \square

We conclude this section with an observation: (H.2c) induces the following scaling relation on $\mathcal{E}_H(\gamma)$

$$\mathcal{E}_H(\lambda\gamma) = \lambda^{\frac{2}{2-\alpha}} \mathcal{E}_H(\gamma) \quad \text{for all } \lambda > 0. \quad (3.12)$$

4 Feynman–Kac formulas and functionals of Brownian Bridges

We derive Feynman–Kac formulas for the moments $\mathbb{E}u^m(t, x)$ for integers $m \geq 2$. These formulas play important roles in proving upper and lower bounds of (1.15) and (1.26).

To discuss our contributions in the current section, let us assume for the moment that \dot{W} is a space-time white noise and $\ell = 1$. The most well-known Feynman–Kac formula for second moment is

$$\mathbb{E}[(u(t, x))^2] = \mathbb{E} \left(\prod_{j=1}^2 u_0(B^j(t) + x) \exp \left\{ \int_0^t \delta(B^1(s) - B^2(s)) ds \right\} \right),$$

where B^1, B^2 are two independent Brownian motions starting at 0. If u_0 is merely a measure, some efforts are needed to make sense of $u_0(B(t) + x)$, which appears on the right-hand side above. An attempt is carried out in [4] using Meyer–Watanabe’s theory of Wiener distributions.

The Feynman–Kac formulas presented here (see (4.10) below) have appeared in [16]. However, there seems to have a minor gap in that article. Namely, Eq. (4.52) there has not been proven if u_0 is a measure. In the current article, we take the chance to fill this gap. Our approach is in the same spirit as [16] and is different from [4]. In particular, we do not make use of Wiener distributions.

Proposition 4.1 *Let u_0 be a measure satisfying (1.13). Then*

$$u(t, x) = \int_{\mathbb{R}^\ell} \mathcal{Z}(z; t, x) u_0(dz). \quad (4.1)$$

In addition, if (H.1) holds, then

$$\frac{\mathcal{Z}(z; t, x)}{p_t(z - x)} = \mathbb{E}_B \exp \left\{ \int_0^t \int_{\mathbb{R}^\ell} \delta \left(B_{0,t}(t - s) + \frac{t-s}{t} z + \frac{s}{t} x - y \right) W(ds, dy) - \frac{t}{2} \gamma(0) \right\}. \quad (4.2)$$

Proof Let $v(t, x)$ be the integral on the right-hand side of (4.1). From (2.7), integrating z with respect to $u_0(dz)$ and applying the stochastic Fubini theorem (cf. [10, Theorem 4.33]), we have

$$\begin{aligned} v(t, x) &= \int_{\mathbb{R}^\ell} p_t(x - z) u_0(dz) + \int_{\mathbb{R}^\ell} \int_0^t \int_{\mathbb{R}^\ell} p_{t-s}(x - y) \mathcal{Z}(z; s, y) W(ds, dy) u_0(dz) \\ &= p_t * u_0(x) + \int_0^t \int_{\mathbb{R}^\ell} p_{t-s}(x - y) v(s, y) W(ds, dy). \end{aligned}$$

Hence, v is a solution of (1.1) with initial datum u_0 . By unicity, Theorem 2.3, we see that $u = v$ and (4.1) follows.

Next, we show (4.2) assuming (H.1). Fix $t > 0$ and $x \in \mathbb{R}^\ell$. For every $u_0 \in C_c^\infty(\mathbb{R}^\ell)$, the following Feynman–Kac formula (see [17, Prop. 5.2] for a general case) holds

$$u(t, x) = \mathbb{E}_B u_0(B(t) + x) \exp \left\{ \int_0^t \int_{\mathbb{R}^\ell} \delta(B(t-s) + x - y) W(ds, dy) - \frac{t}{2} \gamma(0) \right\}.$$

Using the decomposition (2.8) and the fact that $B_{0,t}$ and $B(t)$ are independent, we see that

$$u(t, x) = \int_{\mathbb{R}^\ell} Y(z; t, x) p_t(z) u_0(z + x) dz \quad (4.3)$$

where

$$\begin{aligned} Y(z; t, x) &= \mathbb{E}_B \exp \left\{ \int_0^t \int_{\mathbb{R}^\ell} \delta(B_{0,t}(t-s) + \frac{t-s}{t}z + x - y) W(ds, dy) - \frac{t}{2} \gamma(0) \right\} \\ &= \mathbb{E}_B \exp \{ V_{t,x}(z) \}. \end{aligned}$$

Together with (4.1) we obtain

$$\int_{\mathbb{R}^\ell} \mathcal{Z}(z; t, x) u_0(z) dz = \int_{\mathbb{R}^\ell} Y(z - x; t, x) p_t(z - x) u_0(z) dz$$

for all $u_0 \in C_c^\infty(\mathbb{R}^\ell)$.

Next we show that $z \mapsto Y(z; t, x)$ is continuous. Fix $p > 2$. From the elementary relation $|e^x - e^y| \leq (e^x + e^y)|x - y|$ and the Cauchy–Schwarz inequality, it follows

$$\begin{aligned} \mathbb{E} |Y(z; t, x) - Y(z'; t, x)|^p &\leq \left(\mathbb{E}_W \left(\mathbb{E}_B \left[e^{V_{t,x}(z)} + e^{V_{t,x}(z')} \right]^2 \right)^p \right)^{1/2} \left(\mathbb{E}_W \left(\mathbb{E}_B |V_{t,x}(z) - V_{t,x}(z')|^2 \right)^p \right)^{1/2}. \end{aligned}$$

Since γ is bounded, conditioned on $B_{0,t}$, $V_{t,x}(z)$ is a normal random variable with uniformly (in x, z) bounded variance. It follows that $V_{t,x}(z)$ has uniformly bounded exponential moments. That is,

$$\sup_{z, x \in \mathbb{R}^\ell} \mathbb{E} e^{2pV_{t,x}(z)} \leq C_{p,t}$$

for some constant $C_{p,t}$. We now resort to Minkowski inequality, our exponential bound for $V_{t,x}(z)$ and the relation between L^p and L^2 moments for Gaussian random variables in order to obtain

$$\mathbb{E} |Y(z; t, x) - Y(z'; t, x)|^p \leq C_{p,t} \left(\mathbb{E} |V_{t,x}(z) - V_{t,x}(z')|^2 \right)^{p/2}.$$

In addition, under (H.1), γ is Hölder continuous with order $\kappa > 0$ at 0, it follows that

$$\begin{aligned} & \mathbb{E}|V_{t,x}(z) - V_{t,x}(z')|^2 \\ &= \mathbb{E} \left(\int_0^t \int_{\mathbb{R}^\ell} \delta(B_{0,t}(t-s) + \frac{t-s}{t}z + x - y) W(ds, dy) \right. \\ & \quad \left. - \int_0^t \int_{\mathbb{R}^\ell} \delta(B_{0,t}(t-s) + \frac{t-s}{t}z' + x - y) W(ds, dy) \right)^2 \\ &= \int_0^t \left(\gamma(0) - \gamma\left(\frac{t-s}{t}(z - z')\right) \right) ds \lesssim t|z - z'|^\kappa. \end{aligned}$$

We have shown

$$\mathbb{E}|Y(z; t, x) - Y(z'; t, x)|^p \lesssim |z - z'|^{p\kappa}.$$

Thus, the process $z \mapsto Y(z; t, x)$ has a continuous version. On the other hand, $z \mapsto \mathcal{Z}(z; t, x)$ is also continuous (see Proposition 5.5 below). It follows that $\mathcal{Z}(z; t, x) = Y(z - x; t, x)p_t(z - x)$, which is exactly (4.2). \square

Proposition 4.2 Assuming (H.1), we have

$$\begin{aligned} & \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \\ &= \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z_j - z_k) + \frac{t-s}{t}(x_j - x_k) \right) ds \right\}. \end{aligned} \quad (4.4)$$

and

$$\mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \leq \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) \right) ds \right\}. \quad (4.5)$$

Proof We observe that conditioned on B ,

$$V(z, x) := \int_0^t \int_{\mathbb{R}^\ell} \delta \left(B_{0,t}(t-s) + \frac{t-s}{t}z + \frac{s}{t}x - y \right) W(ds, dy)$$

is a normal random variable with mean zero. In addition, for every $x, x', z, z' \in \mathbb{R}^\ell$, applying (1.23), we have

$$\begin{aligned} & \mathbb{E} \left[V(B^j, z, x) V(B^k, z', x') \middle| B^j, B^k \right] \\ &= \int_0^t \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z - z') + \frac{t-s}{t}(x - x') \right) ds. \end{aligned} \quad (4.6)$$

For every $(x_1, \dots, x_m) \in (\mathbb{R}^\ell)^m$, using (4.2) and (4.6), we have

$$\begin{aligned} & \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \\ &= \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z_j - z_k) + \frac{t-s}{t}(x_j - x_k) \right) ds \right\} \end{aligned} \quad (4.7)$$

Note that in the exponent above, the diagonal terms (with $j = k$) are removed because there are cancellations with the normalization factor $-\frac{t}{2}\gamma(0)$ in (4.2), which occur after taking expectation with respect to W . Finally, apply [16, Lemma 4.1], we obtain (4.5) from (4.7). \square

To extend the previous result to noises satisfying (H.2), we need the following result.

Proposition 4.3 *Assuming (H.2). There exists a constant c depending only on α such that for any $\beta \in (0, 4 \wedge (\ell - \alpha))$,*

$$\left\| \frac{\mathcal{Z}_\varepsilon(x_0; t, x)}{p_t(x - x_0)} - \frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} \right\|_{L^m(\Omega)} \lesssim \varepsilon^{\frac{\beta}{4}} t^{\frac{2-\alpha-\beta}{4}} \sqrt{m} \Theta_t^{\frac{1}{m}}(m) e^{cm \frac{2-\alpha}{2} t} \quad \text{for all } t \geq 0 \quad (4.8)$$

where \mathcal{Z}_ε is the solution to (2.7) with W replaced by W_ε and $\Theta_t(m)$ is defined in (2.10)

Proof Let us put

$$M_s = \sup_{y \in \mathbb{R}^\ell} \frac{\|\mathcal{Z}(x_0; s, y) - \mathcal{Z}_\varepsilon(x_0; s, y)\|_{L^m(\Omega)}}{p_t(y - x_0)}.$$

From (2.7), we have

$$\begin{aligned} \frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} &= 1 + \int_0^t \int_{\mathbb{R}^\ell} \frac{p_{t-s}(x - y) p_s(y - x_0)}{p_t(x - x_0)} \frac{\mathcal{Z}(x_0; s, y)}{p_s(y - x_0)} W(ds, dy) \\ &= 1 + \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}}(y - x_0 - \frac{s}{t}(x - x_0)) \frac{\mathcal{Z}(x_0; s, y)}{p_s(y - x_0)} W(ds, dy), \end{aligned}$$

Then we obtain

$$\begin{aligned} & \left\| \frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} - \frac{\mathcal{Z}_\varepsilon(x_0; t, x)}{p_t(x - x_0)} \right\|_{L^m(\Omega)} \\ & \leq \left\| \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}}(y - x_0 - \frac{s}{t}(x - x_0)) \frac{\mathcal{Z}(x_0; s, y) - \mathcal{Z}_\varepsilon(x_0; s, y)}{p_s(y - x_0)} W(ds, dy) \right\|_{L^m(\Omega)} \\ & \quad + \left\| \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}}(y - x_0 - \frac{s}{t}(x - x_0)) \frac{\mathcal{Z}_\varepsilon(x_0; s, y)}{p_s(y - x_0)} [W(ds, dy) - W_\varepsilon(ds, dy)] \right\|_{L^m(\Omega)} \\ & := I_1 + I_2. \end{aligned}$$

To estimate I_1 , we use Lemma 2.1 and (H.2c) to obtain

$$\begin{aligned} I_1 &\lesssim \sqrt{m} \left(\int_0^t \int_{\mathbb{R}^\ell} e^{-\frac{2s(t-s)}{t} |\xi|^2} \mu(\xi) d\xi M_s^2 ds \right)^{1/2} \\ &\lesssim \sqrt{m} \left(\int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} M_s^2 ds \right)^{1/2}. \end{aligned}$$

To estimate I_2 , we first note that the noise $W - W_\varepsilon$ has spectral density $(1 - e^{-\varepsilon|\xi|^2})^2 \mu(\xi)$. Applying Lemma 2.1, we obtain

$$I_2 \lesssim \sqrt{m} \sup_{s \leq t, y \in \mathbb{R}^\ell} \left\| \frac{\mathcal{Z}_\varepsilon(x_0; s, y)}{p_s(y - x_0)} \right\|_{L^m(\Omega)} \left(\int_0^t \int_{\mathbb{R}^\ell} e^{-\frac{2s(t-s)}{t} |\xi|^2} (1 - e^{-\varepsilon|\xi|^2})^2 \mu(\xi) d\xi ds \right)^{1/2}.$$

Let us fix $\beta \in (0, 4 \wedge (\ell - \alpha))$. Applying the elementary inequality $1 - e^{-\varepsilon|\xi|^2} \leq \varepsilon^{\beta/4} |\xi|^{\beta/2}$ together with the estimate

$$\int_0^t \int_{\mathbb{R}^\ell} e^{-\frac{2s(t-s)}{t} |\xi|^2} |\xi|^\beta \mu(\xi) d\xi ds \lesssim \int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha+\beta}{2}} ds \lesssim t^{\frac{2-\alpha-\beta}{2}},$$

we get

$$I_2 \lesssim \varepsilon^{\frac{\beta}{4}} t^{\frac{2-\alpha-\beta}{4}} \sqrt{m} \sup_{s \leq t, y \in \mathbb{R}^\ell} \left\| \frac{\mathcal{Z}_\varepsilon(x_0; s, y)}{p_s(y - x_0)} \right\|_{L^m(\Omega)}.$$

Reasoning as in [16, Lemma 4.1], we see that

$$\begin{aligned} &\mathbb{E}_B \exp \left\{ \sum_{1 \leq j < k \leq m} \int_0^t \gamma_\varepsilon(B_{0,t}^j(s) - B_{0,t}^k(s)) ds \right\} \\ &\leq \mathbb{E}_B \exp \left\{ \sum_{1 \leq j < k \leq m} \int_0^t \gamma(B_{0,t}^j(s) - B_{0,t}^k(s)) ds \right\}. \end{aligned}$$

Two key observations here are $\gamma_\varepsilon, \gamma$ have spectral measures $\mu(\xi), e^{-\varepsilon|\xi|^2} \mu(\xi)$ respectively and $e^{-\varepsilon|\xi|^2} \mu(\xi) \leq \mu(\xi)$. Hence, it follows from (4.5) and the previous estimate that

$$\sup_{s \leq t, y \in \mathbb{R}^\ell} \left\| \frac{\mathcal{Z}_\varepsilon(x_0; s, y)}{p_s(y - x_0)} \right\|_{L^m(\Omega)} \leq \Theta_t^{\frac{1}{m}}(m).$$

In summary, we have shown

$$M_t \lesssim \sqrt{m} \left(\int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} M_s^2 ds \right)^{\frac{1}{2}} + \varepsilon^{\frac{\beta}{4}} t^{\frac{2-\alpha-\beta}{4}} \sqrt{m} \Theta_t^{\frac{1}{m}}(m).$$

Applying Lemma 2.4, this yields

$$M_t \lesssim \varepsilon^{\frac{\beta}{4}} t^{\frac{2-\alpha-\beta}{4}} \sqrt{m} \Theta_t^{\frac{1}{m}}(m) e^{cm^{\frac{2}{2-\alpha}} t} \quad \text{for all } t \geq 0, \quad (4.9)$$

for some constant c depending only on α . \square

We are now ready to derive Feynman–Kac formulas for positive moments.

Proposition 4.4 *Let u_0 be a measure satisfying (1.13). Under (H.1) or (H.2), for every $x_1, \dots, x_m \in \mathbb{R}^\ell$, we have*

$$\begin{aligned} \mathbb{E} \left[\prod_{j=1}^m u(t, x_j) \right] &= \int_{(\mathbb{R}^\ell)^m} \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) \right. \right. \\ &\quad \left. \left. + x_j - x_k + \frac{s}{t} (y_j - y_k) \right) ds \right\} \\ &\quad \times \prod_{j=1}^m [p_t(y_j) u_0(x_j + dy_j)]. \end{aligned} \quad (4.10)$$

and

$$\mathbb{E} \left[\prod_{j=1}^m \frac{u(t, x_j)}{p_t * |u_0|(x_j)} \right] \leq \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) \right) ds \right\}. \quad (4.11)$$

Proof We prove the result under the hypothesis (H.2). The proof under hypothesis (H.1) is easier and omitted.

Step 1: we first consider (4.10) and (4.11) when the initial data are Dirac masses. More precisely, we will show that

$$\begin{aligned} \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \\ = \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t} (z_j - z_k) + \frac{t-s}{t} (x_j - x_k) \right) ds \right\}, \end{aligned} \quad (4.12)$$

and

$$\mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \leq \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) \right) ds \right\}. \quad (4.13)$$

Fix $\varepsilon > 0$, identity (4.12) with \mathcal{Z}, γ replaced by $\mathcal{Z}_\varepsilon, \gamma_\varepsilon$ has been obtained in (4.4). Namely, we have

$$\begin{aligned} & \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}_\varepsilon(z_j; t, x_j)}{p_t(x_j - z_j)} \right] \\ &= \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma_\varepsilon \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z_j - z_k) + \frac{t-s}{t}(x_j - x_k) \right) ds \right\} \end{aligned} \quad (4.14)$$

Using analogous arguments to [16, Proposition 4.2], we can show that for every $\kappa \in \mathbb{R}$, as $\varepsilon \downarrow 0$, the functions

$$(x_1, z_1, \dots, x_m, z_m) \mapsto \mathbb{E} \exp \left\{ \kappa \int_0^t \sum_{1 \leq j < k \leq m} \gamma_\varepsilon \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z_j - z_k) + \frac{t-s}{t}(x_j - x_k) \right) ds \right\}$$

converge uniformly on $\mathbb{R}^{2m\ell}$ to the function

$$(x_1, z_1, \dots, x_m, z_m) \mapsto \mathbb{E} \exp \left\{ \kappa \int_0^t \sum_{1 \leq j < k \leq m} \gamma \left(B_{0,t}^j(s) - B_{0,t}^k(s) + \frac{s}{t}(z_j - z_k) + \frac{t-s}{t}(x_j - x_k) \right) ds \right\}.$$

In addition, in view of Proposition 4.3,

$$\lim_{\varepsilon \downarrow 0} \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}_\varepsilon(z_j; t, x_j)}{p_t(x_j - z_j)} \right] = \mathbb{E} \left[\prod_{j=1}^m \frac{\mathcal{Z}(z_j; t, x_j)}{p_t(x_j - z_j)} \right].$$

Sending $\varepsilon \downarrow 0$ in (4.14), we obtain (4.12). The estimate (4.13) is obtained analogously using (4.5). We omit the details.

Step 2: For general initial data satisfying (1.13), we note that from (4.1),

$$\prod_{j=1}^m u(t, x_j) = \int_{(\mathbb{R}^\ell)^m} \prod_{j=1}^m [\mathcal{Z}(z_j; t, x_j) u_0(dz_j)].$$

From here, it is evident that (4.10), (4.11) are consequences of (4.12), (4.13) and Fubini's theorem. \square

We conclude this section with the following observation.

Remark 4.5 Under (H.1), it is evident from (4.2) that $\mathcal{Z}(z; t, x)$ is non-negative for every z, t, x . Under (H.2), thanks to Proposition 4.3, $\mathcal{Z}(z; t, x)$ is the limit of non-negative random variables, hence $\mathcal{Z}(z; t, x)$ is also non-negative for every z, t, x . Furthermore, in view of (4.1), if u_0 is non-negative then $u(t, x)$ is non-negative for every t, x .

5 Moment asymptotic and regularity

Moment asymptotic

We begin with a study on high moments. Under hypothesis (H.1), the high moment asymptotic is governed by the value of γ at the origin.

Proposition 5.1 Under (H.1), for every $T > 0$, we have

$$\limsup_{m \rightarrow \infty} m^{-2} \log \sup_{0 < t \leq T} \sup_{x \in \mathbb{R}} \mathbb{E} \left(\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} \right)^m \leq \frac{T}{2} \gamma(0). \quad (5.1)$$

Proof Since γ is positive definite, $\gamma(x) \leq \gamma(0)$ for all $x \in \mathbb{R}^\ell$. It follows from (4.11) that

$$\mathbb{E} \left(\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} \right)^m \leq \exp \left(\frac{m(m-1)}{2} t \gamma(0) \right).$$

This immediately yields (5.1). \square

The following intermediate result will be applied to the measure $e^{-2\varepsilon|\xi|^2} \mu(d\xi)$ to obtain moment asymptotic under (H.2).

Lemma 5.2 Suppose that $\mu(\mathbb{R}^\ell) < \infty$. For each t, T, m , we put $t_m = m^{\frac{2}{2-\alpha}} t$ and $T_m = m^{\frac{2}{2-\alpha}} T$. Then

$$\limsup_{m \rightarrow \infty} \frac{1}{m T_m} \log \sup_{0 \leq t \leq T} \mathbb{E} \exp \left(\frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{t_m} \gamma \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right) \leq \frac{1}{2} \mathcal{E}_H(\gamma). \quad (5.2)$$

Proof The condition $\mu(\mathbb{R}^\ell) < \infty$ implies that the inverse Fourier transform of $\mu(\xi)$ exists and is a bounded continuous function γ . Furthermore, $\max_{x \in \mathbb{R}^\ell} \gamma(x) = \gamma(0)$. For each $\lambda \in (0, 1)$, we note that

$$\begin{aligned} & \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{t_m} \gamma \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right\} \\ & \leq e^{\frac{(m-1)t_m}{2} \gamma(0)(1-\lambda)} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda t_m} \gamma \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right\}. \end{aligned}$$

Using (2.9), we see that the expectation above is at most

$$(1 - \lambda)^{-\frac{m\ell}{2}} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda t_m} \gamma (B^j(s) - B^k(s)) ds \right\}.$$

In addition, reasoning as in [16, Lemma 4.1], we see that

$$\begin{aligned} & \sup_{0 \leq t \leq T} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda t_m} \gamma (B^j(s) - B^k(s)) ds \right\} \\ &= \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda T_m} \gamma (B^j(s) - B^k(s)) ds \right\}. \end{aligned}$$

It follows that

$$\begin{aligned} & \limsup_{m \rightarrow \infty} \frac{1}{m T_m} \log \sup_{0 \leq t \leq T} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{t_m} \gamma (B_{0,t_m}^j(s) - B_{0,t_m}^k(s)) ds \right\} \\ & \leq \frac{1 - \lambda}{2} \gamma(0) + \limsup_{m \rightarrow \infty} \frac{1}{m T_m} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda T_m} \gamma (B^j(s) - B^k(s)) ds \right\}, \end{aligned}$$

where we have used the fact that $\lim_{m \rightarrow \infty} \frac{1}{m T_m} \log(1 - \lambda)^{-\frac{m\ell}{2}} = 0$. Applying [8, Theorem 1.1], we get

$$\limsup_{m \rightarrow \infty} \frac{1}{m \lambda T_m} \mathbb{E} \exp \left\{ \frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{\lambda T_m} \gamma (B^j(s) - B^k(s)) ds \right\} \leq \frac{1}{2} \mathcal{E}_H(\gamma).$$

Thus we have shown

$$\begin{aligned} & \limsup_{m \rightarrow \infty} \frac{1}{m T_m} \log \sup_{0 \leq t \leq T} \mathbb{E} \exp \left(\frac{1}{m} \sum_{1 \leq j < k \leq m} \int_0^{t_m} \gamma (B_{0,t_m}^j - B_{0,t_m}^k(s)) ds \right) \\ & \leq \frac{\lambda}{2} \mathcal{E}_H(\gamma) + \frac{1 - \lambda}{2} \gamma(0). \end{aligned}$$

Finally, we send $\lambda \rightarrow 1^-$ to finish the proof. \square

Proposition 5.3 Assuming (H.2), for every fixed $T > 0$,

$$\lim_{m \rightarrow \infty} m^{-\frac{4-\alpha}{2-\alpha}} \log \sup_{0 \leq t \leq T} \sup_{x \in \mathbb{R}^\ell} \mathbb{E} \left(\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} \right)^m \leq \frac{T}{2} \mathcal{E}_H(\gamma) \quad (5.3)$$

where $\mathcal{E}_H(\gamma)$ is the Hartree energy defined in (3.1).

Proof Applying inequality (4.11), we have

$$\sup_{x \in \mathbb{R}^\ell} \mathbb{E} \left(\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} \right)^m \leq \mathbb{E} \exp \left\{ \int_0^t \sum_{1 \leq j < k \leq m} \gamma(B_{0,t}^j(s) - B_{0,t}^k(s)) ds \right\}.$$

In addition, by the change of variable $s \rightarrow sm^{-\frac{2}{2-\alpha}}$ and the scaling property of Brownian bridge, $\{B_{0,\lambda t}(\lambda s), s \in [0, t]\} \stackrel{\text{law}}{=} \{\sqrt{\lambda} B_{0,t}(s), s \in [0, t]\}$, the right hand side in the above expression is the same as

$$\mathbb{E} \exp \left\{ \frac{1}{m} \int_0^{m^{\frac{2}{2-\alpha}} t} \sum_{1 \leq j < k \leq m} \gamma \left(B_{0, m^{\frac{2}{2-\alpha}} t}^j(s) - B_{0, m^{\frac{2}{2-\alpha}} t}^k(s) \right) ds \right\}.$$

Hence, denoting $t_m = m^{\frac{2}{2-\alpha}} t$ and $T_m = m^{\frac{2}{2-\alpha}} T$, we see that (5.3) is equivalent to the statement

$$\begin{aligned} & \limsup_{m \rightarrow \infty} \frac{1}{m T_m} \log \sup_{0 < t_m \leq T_m} \mathbb{E} \exp \left\{ \frac{1}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} \gamma(B_{0,t_m}^j(s) - B_{0,t_m}^k(s)) ds \right\} \\ & \leq \frac{1}{2} \mathcal{E}_H(\gamma). \end{aligned} \quad (5.4)$$

Let $p, q > 1$ such that $p^{-1} + q^{-1} = 1$. By Hölder inequality

$$\mathbb{E} \exp \left\{ \frac{1}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} \gamma(B_{0,t_m}^j(s) - B_{0,t_m}^k(s)) ds \right\} \leq \mathcal{A}^{\frac{1}{p}} \mathcal{B}^{\frac{1}{q}}$$

where

$$\begin{aligned} \mathcal{A} &= \sup_{0 < t_m \leq T_m} \mathbb{E} \exp \left\{ \frac{p}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} \gamma_\varepsilon(B_{0,t_m}^j(s) - B_{0,t_m}^k(s)) ds \right\} \\ \mathcal{B} &= \sup_{0 < t_m \leq T_m} \mathbb{E} \exp \left\{ \frac{q}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon)(B_{0,t_m}^j(s) - B_{0,t_m}^k(s)) ds \right\}. \end{aligned}$$

From Lemma 5.2 and the fact that $\mathcal{E}_H(\gamma_\varepsilon) \leq \mathcal{E}_H(\gamma)$ (see (3.3)), we have

$$\lim_{p \rightarrow 1^+} \limsup_{m \rightarrow \infty} \frac{1}{m T_m} \log \mathcal{A} \leq \frac{1}{2} \mathcal{E}_H(\gamma).$$

Hence, it suffices to show for every fixed $q > 1$,

$$\lim_{\varepsilon \downarrow 0} \limsup_{m \rightarrow \infty} \frac{1}{mT_m} \log \mathcal{B} = 0. \quad (5.5)$$

By Cauchy–Schwarz inequality and the fact that $B_{0,t} \stackrel{\text{law}}{=} B_{0,t}(t - \cdot)$, we have

$$\begin{aligned} & \mathbb{E} \exp \left\{ \frac{q}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon) \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right\} \\ & \leq \mathbb{E} \exp \left\{ \frac{2q}{m} \int_0^{\frac{t_m}{2}} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon) \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right\}, \end{aligned}$$

Together with (2.9), we arrive at

$$\begin{aligned} & \mathbb{E} \exp \left\{ \frac{q}{m} \int_0^{t_m} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon) \left(B_{0,t_m}^j(s) - B_{0,t_m}^k(s) \right) ds \right\} \\ & \leq 2^{m\ell} \mathbb{E} \exp \left\{ \frac{2q}{m} \int_0^{\frac{t_m}{2}} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon) \left(B^j(s) - B^k(s) \right) ds \right\}. \end{aligned}$$

Note that the right hand side of the above inequality is the m -th moment of the solution to the Eq. (1.1) driven by the noise with spatial covariance $\frac{2q}{m}(\gamma - \gamma_\varepsilon)$, i.e., $\mathbb{E} u(\frac{t_m}{2}, x)^m$, the initial condition is $u_0(x) \equiv 2^\ell$. Using the hyper-contractivity as in [16, 19], we have

$$\begin{aligned} & \mathbb{E} \exp \left\{ \frac{2q}{m} \int_0^{\frac{t_m}{2}} \sum_{1 \leq j < k \leq m} (\gamma - \gamma_\varepsilon) \left(B^j(s) - B^k(s) \right) ds \right\} \\ & \leq \left[\mathbb{E} \exp \left\{ \frac{2q(m-1)}{m} \int_0^{\frac{t_m}{2}} (\gamma - \gamma_\varepsilon) \left(B^1(s) - B^2(s) \right) ds \right\} \right]^{\frac{m}{2}} \\ & \leq \left[\sum_{k=0}^{\infty} (2q)^k \int_{[0, \frac{t_m}{2}]^k} \int_{\mathbb{R}^{\ell k}} \prod_{j=1}^k \left(e^{-|\eta_j|^2} (s_{j+1} - s_j)^{-\frac{\alpha}{2}} \right) \right. \\ & \quad \left. \prod_{j=1}^k \left(1 - e^{-\varepsilon(s_{j+1} - s_j)^{-1} |\eta_j|^2} \right) \mu(\eta) d\eta ds \right]^{\frac{m}{2}} \end{aligned}$$

where in the last line we have used the estimate (3.7) in [15], $[0, \frac{t_m}{2}]^k = \{(s_1, \dots, s_k) \in [0, \frac{t_m}{2}]^k : s_1 < \dots < s_k\}$ and $\mu(\eta) d\eta ds$ is abbreviation for $\prod_{j=1}^k \mu(\eta_j) d\eta_j ds_j$. Since

$\alpha < 2$, we can find a $\beta > 0$ such that $\beta < 1 - \frac{\alpha}{2}$. Then using the elementary inequality

$$1 - e^{-x} \leq C_\beta x^\beta \quad \forall x > 0,$$

and asymptotic behavior of Mittag-Leffler function ([12, p. 208]), we obtain

$$\begin{aligned} & \sum_{k=0}^{\infty} (2q)^k \int_{[0, \frac{t_m}{2}]^k} \int_{\mathbb{R}^{\ell k}} \prod_{j=1}^k \left(e^{-|\eta_j|^2} (s_{j+1} - s_j)^{-\frac{\alpha}{2}} \right) \prod_{j=1}^k \left(1 - e^{-\varepsilon(s_{j+1} - s_j)^{-1} |\eta_j|^2} \right) \mu(\eta) d\eta ds \\ & \leq \sum_{k=0}^{\infty} (C_\beta 2q \varepsilon^\beta)^k \int_{[0, \frac{t_m}{2}]^k} \int_{\mathbb{R}^{\ell k}} \prod_{j=1}^k \left(e^{-|\eta_j|^2} |\eta_j|^{2\beta} \right) (s_{j+1} - s_j)^{-\frac{\alpha}{2} - \beta} \mu(\eta) d\eta ds \\ & \leq \sum_{k=0}^{\infty} \frac{(Cq)^k t_m^{(-\frac{\alpha}{2} - \beta + 1)k} \varepsilon^{k\beta}}{\Gamma((-\frac{\alpha}{2} - \beta + 1)k + 1)} \leq C \exp \left(ct_m \varepsilon^{-\frac{\beta}{-\frac{\alpha}{2} - \beta + 1}} \right). \end{aligned}$$

Hence, we have shown

$$\mathcal{B} \leq C^m \exp \left(m T_m \varepsilon^{-\frac{\beta}{-\frac{\alpha}{2} - \beta + 1}} \right),$$

from which (5.5) follows. The proof for (5.3) is complete. \square

Hölder continuity

We investigate the regularity of the process $\frac{\mathcal{Z}(x; t, y)}{p_t(y-x)}$ in the variables x and y . These properties will be used in the proof of upper bound. For each integer $m \geq 2$ and $t > 0$, we recall that $\Theta_t(m)$ is defined in (2.10).

Note that from Proposition 4.4, we have

$$\sup_{s \in (0, t]} \sup_{x, y_1, \dots, y_m \in \mathbb{R}^\ell} \mathbb{E} \prod_{j=1}^m \frac{\mathcal{Z}(x; s, y_j)}{p_s(y_j - x)} = \Theta_t(m). \quad (5.6)$$

Lemma 5.4 *For every $r > 0$ and $y_1, y_2 \in \mathbb{R}^\ell$*

$$\|p_r(\cdot - y_1) - p_r(\cdot - y_2)\|_{\mathcal{H}_0}^2 \leq C r^{-\frac{\alpha}{2}} \left(\frac{|y_2 - y_1|}{r^{1/2}} \wedge 1 \right)$$

under (H.2); and

$$\|p_r(\cdot - y_1) - p_r(\cdot - y_2)\|_{\mathcal{H}_0}^2 \leq C \left(\frac{|y_2 - y_1|^2}{r} \wedge 1 \right)$$

under (H.1). In the above, the constant C does not depend on y_1, y_2 nor r .

Proof We denote $f(\cdot) = |p_r(\cdot - y_1) - p_r(\cdot - y_2)|$. Assuming first (H.2), we observe the following simple estimate

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} f(y)f(z)\gamma(y-z)dydz \leq \sup_{z \in \mathbb{R}^\ell} |f * \gamma(z)| \int_{\mathbb{R}^\ell} f(y)dy.$$

Noting that

$$\sup_{z \in \mathbb{R}^\ell} |f * \gamma(z)| \leq 2 \sup_{z \in \mathbb{R}^\ell} |p_r * \gamma(z)| = 2p_r * \gamma(0) \lesssim r^{-\frac{\alpha}{2}}$$

and

$$\int_{\mathbb{R}^\ell} f(y)dy \lesssim \left(\frac{|y_2 - y_1|}{r^{1/2}} \wedge 1 \right), \quad (5.7)$$

the result easily follows. Under (H.1), we used the following inequality

$$\iint_{\mathbb{R}^\ell \times \mathbb{R}^\ell} f(y)f(z)\gamma(y-z)dydz \leq \gamma(0) \left(\int_{\mathbb{R}^\ell} f(y)dy \right)^2$$

together with (5.7) to obtain the result. \square

Proposition 5.5 Assuming (H.1) or (H.2). There exists a constant $\eta \in (0, 1)$ such that for every compact set K and every integer $m \geq 2$,

$$\sup_{w \in \mathbb{R}^\ell} \left\| \sup_{\substack{x_1, x_2 \in K, \\ y \in B(w, 1)}} \frac{\left| \frac{\mathcal{Z}(x_1; t, y)}{p_t(y-x_1)} - \frac{\mathcal{Z}(x_2; t, y)}{p_t(y-x_2)} \right|}{|x_2 - x_1|^\eta} \right\|_{L^m(\Omega)} \leq c_K(t) m^{\frac{1}{2}} [\Theta_t(m)]^{\frac{1}{m}} e^{cm \frac{2}{2-\alpha}}, \quad (5.8)$$

and

$$\sup_{w, x \in \mathbb{R}^\ell} \left\| \sup_{y_1, y_2 \in B(w, 1)} \frac{\left| \frac{\mathcal{Z}(x; t, y_1)}{p_t(y_1-x)} - \frac{\mathcal{Z}(x; t, y_2)}{p_t(y_2-x)} \right|}{|y_2 - y_1|^\eta} \right\|_{L^m(\Omega)} \leq c_K(t) m^{\frac{1}{2}} [\Theta_t(m)]^{\frac{1}{m}}, \quad (5.9)$$

where $B(w, 1)$ is the closed unit ball in \mathbb{R}^ℓ centered at w . In the above, the constant c depends only on $\bar{\alpha}$ and η and $c_K(t)$ depends only on K, t, η .

Proof We present the proof under hypothesis (H.2) in detail. The proof for the other case is similar and is omitted. We first show that for every $\eta \in (0, 2 - \alpha)$,

$$\sup_{x \in \mathbb{R}^\ell} \left\| \frac{\mathcal{Z}(x_1; t, x)}{p_t(x - x_1)} - \frac{\mathcal{Z}(x_2; t, x)}{p_t(x - x_2)} \right\|_{L^m(\Omega)} \lesssim_t \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} |x_2 - x_1|^{\frac{\eta}{2}} e^{cm \frac{2}{2-\alpha}}. \quad (5.10)$$

In the above, we have added a subscript t to \lesssim to emphasize that the implied constant depends on t . Fix $t > 0$ and $x_1, x_2, x \in \mathbb{R}^\ell$. From (2.7), we have

$$\begin{aligned} \frac{\mathcal{Z}(x_1; t, x)}{p_t(x - x_1)} - \frac{\mathcal{Z}(x_2; t, x)}{p_t(x - x_2)} &= \int_0^t \int_{\mathbb{R}^\ell} f(s, y) \frac{\mathcal{Z}(x_1; s, y)}{p_s(y - x_1)} W(ds, dy) \\ &+ \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}} \left(y - x_2 - \frac{s}{t}(x - x_2) \right) \left[\frac{\mathcal{Z}(x_2; s, y)}{p_t(y - x_2)} - \frac{\mathcal{Z}(x_1; s, y)}{p_t(y - x_1)} \right] W(ds, dy) \end{aligned} \quad (5.11)$$

where

$$f(s, y) = p_{\frac{s(t-s)}{t}} \left(y - x_1 - \frac{s}{t}(x - x_1) \right) - p_{\frac{s(t-s)}{t}} \left(y - x_2 - \frac{s}{t}(x - x_2) \right).$$

Obviously f also depends on t, x_1, x_2 and x , however these parameters will be omitted. For each integer $m \geq 2$, applying Lemma 2.1 we see that

$$\left\| \int_0^t \int_{\mathbb{R}^\ell} f(s, y) \frac{\mathcal{Z}(x_1; s, y)}{p_s(y - x_1)} W(ds, dy) \right\|_{L^m(\Omega)} \leq \sqrt{4m} [\Theta_t(m)]^{\frac{1}{m}} \|f(s, y) \mathbf{1}_{[0, t]}(s)\|_{\mathfrak{H}_{s, y}}.$$

Applying Lemma 5.4, for every $\eta \in (0, 2 - \alpha)$, there exists $c_\eta > 0$ such that

$$\|f(s, y) \mathbf{1}_{[0, t]}(s)\|_{\mathfrak{H}_{s, y}} \leq c_\eta t^{\frac{1}{2} - \frac{\alpha + \eta}{4}} |x_2 - x_1|^{\frac{\eta}{2}}.$$

Hence,

$$\left\| \int_0^t \int_{\mathbb{R}^\ell} f(s, y) \frac{\mathcal{Z}(x_1; s, y)}{p_s(y - x_1)} W(ds, dy) \right\|_{L^m(\Omega)} \leq c_\eta t^{\frac{1}{2} - \frac{\alpha + \eta}{4}} \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} |x_2 - x_1|^{\frac{\eta}{2}}. \quad (5.12)$$

For each $s > 0$, we set

$$M_s = \sup_{x \in \mathbb{R}^\ell} \left\| \frac{\mathcal{Z}(x_1; s, x)}{p_s(x - x_1)} - \frac{\mathcal{Z}(x_2; s, x)}{p_s(x - x_2)} \right\|_{L^m(\Omega)}.$$

It follows from Lemma 2.1 that

$$\begin{aligned} &\left\| \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}} \left(y - x_2 - \frac{s}{t}(x - x_2) \right) \left[\frac{\mathcal{Z}(x_2; s, y)}{p_t(y - x_2)} - \frac{\mathcal{Z}(x_1; s, y)}{p_t(y - x_1)} \right] W(ds, dy) \right\|_{L^m(\Omega)} \\ &\leq c\sqrt{m} \left(\int_0^t \left\| p_{\frac{s(t-s)}{t}} \left(\cdot - x_2 - \frac{s}{t}(x - x_2) \right) \right\|_{\mathfrak{H}_0}^2 M_s^2 ds \right)^{\frac{1}{2}} \\ &= c\sqrt{m} \left(\int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} M_s^2 ds \right)^{\frac{1}{2}}, \end{aligned}$$

where c is some constant. Applying these estimates in (5.11) yields

$$M_t \leq c_\eta t^{\frac{1}{2} - \frac{\alpha + \eta}{2}} \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} |x_2 - x_1|^{\frac{\eta}{2}} + c \sqrt{m} \left(\int_0^t \left(\frac{s(t-s)}{t} \right)^{-\frac{\alpha}{2}} M_s^2 ds \right)^{\frac{1}{2}}.$$

We now apply Lemma 2.4 to get

$$M_t \lesssim_t \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} |x_2 - x_1|^{\frac{\eta}{2}} e^{cm^{\frac{2}{2-\alpha}}},$$

which is exactly (5.10).

To complete the proof of the estimate (5.8). Fix $t > 0$ and $x_1, x_2, y_1, y_2 \in \mathbb{R}^\ell$. Observe that

$$\begin{aligned} & \frac{\mathcal{Z}(x_1; t, y_1)}{p_t(y_1 - x_1)} - \frac{\mathcal{Z}(x_2; t, y_2)}{p_t(y_2 - x_2)} \\ &= \int_0^t \int_{\mathbb{R}^\ell} g(s, y) \frac{\mathcal{Z}(x_1; s, y)}{p_s(y - x_1)} W(ds, dy) \\ &+ \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}} \left(y - x_2 - \frac{s}{t}(y_2 - x_2) \right) \left[\frac{\mathcal{Z}(x_2; s, y)}{p_t(y - x_2)} - \frac{\mathcal{Z}(x_1; s, y)}{p_t(y - x_1)} \right] W(ds, dy) \\ &= I_1 + I_2, \end{aligned}$$

where

$$g(s, y) = p_{\frac{s(t-s)}{t}} \left(y - x_1 - \frac{s}{t}(y_1 - x_1) \right) - p_{\frac{s(t-s)}{t}} \left(y - x_2 - \frac{s}{t}(y_2 - x_2) \right).$$

Similar to (5.12), we have

$$\|I_1\|_{L^m(\Omega)} \lesssim_t \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} (|x_2 - x_1| + |y_2 - y_1|)^{\frac{\eta}{2}}. \quad (5.13)$$

I_2 can be estimated using Lemma 2.1 and (5.10)

$$\|I_2\|_{L^m(\Omega)} \lesssim_t \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} |x_2 - x_1|^{\frac{\eta}{2}} e^{cm^{\frac{2}{2-\alpha}}}.$$

Hence, we have shown

$$\left\| \frac{\mathcal{Z}(x_1; t, y_1)}{p_t(y_1 - x_1)} - \frac{\mathcal{Z}(x_2; t, y_2)}{p_t(y_2 - x_2)} \right\|_{L^m(\Omega)} \lesssim_t \sqrt{m} [\Theta_t(m)]^{\frac{1}{m}} (|x_2 - x_1| + |y_2 - y_1|)^{\frac{\eta}{2}} e^{cm^{\frac{2}{2-\alpha}}}.$$

At this point, the estimate (5.8) follows from the Garsia-Rodemich-Rumsey inequality (cf. [13]).

The proof of (5.9) is simpler. Actually, by writing

$$\frac{\mathcal{Z}(x; t, y_1)}{p_t(y_1 - x)} - \frac{\mathcal{Z}(x; t, y_2)}{p_t(y_2 - x)}$$

$$= \int_0^t \int_{\mathbb{R}^\ell} \left(p_{\frac{s(t-s)}{t}} \left(y - x - \frac{s}{t}(y_1 - x) \right) - p_{\frac{s(t-s)}{t}} \left(y - x - \frac{s}{t}(y_2 - x) \right) \right) \frac{\mathcal{Z}(x; s, y)}{p_s(y - x)} W(ds, dy),$$

we get an estimate for $\left\| \frac{\mathcal{Z}(x; t, y_1)}{p_t(y_1 - x)} - \frac{\mathcal{Z}(x; t, y_2)}{p_t(y_2 - x)} \right\|_{L^m(\Omega)}$ as in (5.13). The estimate (5.9) again follows from the Garsia-Rodemich-Rumsey inequality (cf. [13]). We omit the details. \square

In proving (1.26), we need to handle the asymptotic of $\sup_{\varepsilon < 1} \sup_{x \in K, |y| \leq R} \frac{\mathcal{Z}_\varepsilon(x; t, y)}{p_t(y - x)}$, thus we write down the Hölder continuity result for $\frac{\mathcal{Z}_\varepsilon(x; t, y)}{p_t(y - x)}$ with respect to ε, x, y . The proof is similar to Proposition 5.5 and is left to the reader.

Proposition 5.6 *Assuming (H.1) or (H.2). There exists a constant $\eta \in (0, 1)$ such that for every compact set K and every integer $m \geq 2$,*

$$\sup_{w \in \mathbb{R}^\ell} \left\| \sup_{\substack{x_1, x_2 \in K, y \in B(w, 1) \\ \varepsilon, \varepsilon' \in (0, 1)}} \frac{\left| \frac{\mathcal{Z}_\varepsilon(x_1; t, y)}{p_t(y - x_1)} - \frac{\mathcal{Z}_{\varepsilon'}(x_2; t, y)}{p_t(y - x_2)} \right|}{(|x_2 - x_1| + |\varepsilon - \varepsilon'|)^\eta} \right\|_{L^m(\Omega)} \leq c_K(t) m^{\frac{1}{2}} [\Theta_t(m)]^{\frac{1}{m}} e^{cm^{\frac{2}{2-\alpha}}}, \quad (5.14)$$

and

$$\sup_{w, x \in \mathbb{R}^\ell; \varepsilon \leq 1} \left\| \sup_{y_1, y_2 \in B(w, 1)} \frac{\left| \frac{\mathcal{Z}_\varepsilon(x; t, y_1)}{p_t(y_1 - x)} - \frac{\mathcal{Z}_\varepsilon(x; t, y_2)}{p_t(y_2 - x)} \right|}{|y_2 - y_1|^\eta} \right\|_{L^m(\Omega)} \leq c_K(t) m^{\frac{1}{2}} [\Theta_t(m)]^{\frac{1}{m}}. \quad (5.15)$$

In the above, the constant c depends only on $\bar{\alpha}$ and η and $c_K(t)$ depends only on K, t, η .

6 Spatial asymptotic

In this section we study the asymptotic of

$$\sup_{|y| \leq R} \frac{u(t, y)}{p_t * u_0(y)}$$

as described in Theorems 1.3, 1.4 and 1.5. In what follows, we denote

$$a = \frac{2}{4 - \bar{\alpha}} \quad (6.1)$$

where we recall that $\bar{\alpha}$ is defined in (1.19). Since $0 \leq \bar{\alpha} < 2$, a ranges inside the interval $[1/2, 1)$. Because $R \mapsto \sup_{|y| \leq R} \frac{u(t, y)}{p_t * u_0(y)}$ is monotone, it suffices to show these results along lattice sequence $R \in \{e^n\}_{n \geq 1}$.

6.1 The upper bound

This subsection is devoted to the proof of upper bounds in Theorems 1.3 and 1.4 by combining the moment asymptotic bounds and the regularity estimates obtained in Sect. 5. We also recall that $\Theta_t(m)$ is defined in (2.10). Propositions 5.1, 5.3 together with (5.6) imply

$$\limsup_{m \rightarrow \infty} m^{-\frac{4-\bar{\alpha}}{2-\bar{\alpha}}} \log \Theta_t(m) \leq \frac{t}{2} \mathcal{E}, \quad (6.2)$$

where \mathcal{E} is defined in (1.19). The following result gives an upper bound for spatial asymptotic of $\mathcal{Z}(x; \cdot, \cdot)$.

Theorem 6.1 *For every compact set K , we have*

$$\limsup_{n \rightarrow \infty} n^{-a} \sup_{x \in K, |y| \leq e^n} \left(\log \mathcal{Z}(x; t, y) + \frac{|y-x|^2}{2t} \right) \leq \frac{4-\bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{\mathcal{E}}{2-\bar{\alpha}} t \right)^{1-a} \quad (6.3)$$

Proof We begin by noting that according to Remark 4.5, $\mathcal{Z}(x; t, y)$ is non negative a.s. for each x, y, t . Let t be fixed and put

$$\mathcal{K}(x, y) = \frac{\mathcal{Z}(x; t, y)}{p_t(y-x)},$$

where we have omitted the dependence on t . For every $n > 1$ and every $\lambda > 0$, we consider the probability

$$P_n := P \left(\sup_{x \in K, |y| \leq e^n} \log \mathcal{K}(x, y) > \lambda n^a \right).$$

Let b be a fixed number such that $a < b < 1$. We can find the points $x_i, i = 1, \dots, M_n$, such that $K \subset \cup_{i=1}^{M_n} B(x_i, e^{-n^b})$ and $M_n \lesssim e^{\ell n^b}$. In addition, by partitioning the ball $B(0, e^n)$ into unit balls, we see that P_n is at most

$$c(\ell) e^{\ell n + \ell n^b} \sup_{w \in \mathbb{R}^\ell, x_i} P \left(\sup_{x \in B(x_i, e^{-n^b}), y \in B(w, 1)} \mathcal{K}(x, y) > e^{\lambda n^a} \right).$$

Applying Chebychev inequality, we see that

$$P \left(\sup_{x \in B(x_i, e^{-n^b}), y \in B(w, 1)} \mathcal{K}(x, y) > e^{\lambda n^a} \right) \leq e^{-\lambda m n^a} \left\| \sup_{x \in B(x_i, e^{-n^b}), y \in B(w, 1)} \mathcal{K}(x, y) \right\|_{L^m(\Omega)}^m.$$

The above m -th moment is estimated by triangle inequality

$$\begin{aligned}
 & \left\| \sup_{x \in B(x_i, e^{-n^b}), y \in B(w, 1)} \mathcal{K}(x, y) \right\|_{L^m(\Omega)}^m \\
 & \leq 3^m \left\| \sup_{x \in B(x_i, e^{-n^b}), y \in B(w, 1)} |\mathcal{K}(x, y) - \mathcal{K}(x_i, y)| \right\|_{L^m(\Omega)}^m \\
 & \quad + 3^m \left\| \sup_{y \in B(w, 1)} |\mathcal{K}(x_i, y) - \mathcal{K}(x_i, w)| \right\|_{L^m(\Omega)}^m \\
 & \quad + 3^m \|\mathcal{K}(x_i, w)\|_{L^m(\Omega)}^m \\
 & := 3^m (I_1 + I_2 + I_3).
 \end{aligned}$$

Using Proposition 5.5 and (5.6), we see that

$$I_1 \lesssim e^{-\eta mn^b + cm^{\frac{1}{1-a}}} \Theta_t(m), \quad I_2 \lesssim m^{\frac{m}{2}} \Theta_t(m), \quad I_3 \leq \Theta_t(m).$$

Altogether, we have

$$P_n \lesssim 3^m e^{\ell n^b + \ell n - \lambda mn^a} \left(e^{-\eta mn^b + cm^{\frac{1}{1-a}}} \Theta_t(m) + m^{\frac{m}{2}} \Theta_t(m) \right). \quad (6.4)$$

For each $\beta > 0$, we choose $m = \lfloor \beta n^{1-a} \rfloor$. In addition, for every fixed $\varepsilon > 0$, (6.2) yields

$$\log \Theta_t(\lfloor \beta n^{1-a} \rfloor) \leq \left(\frac{t}{2} \mathcal{E} + \varepsilon \right) \beta^{\frac{1}{1-a}} n \quad (6.5)$$

for all n sufficiently large. It follows from (6.4) and (6.5) that

$$\sum_{n=1}^{\infty} P \left(\sup_{x \in K, |y| \leq e^n} \log \mathcal{K}(x, y) > \lambda n^a \right) \lesssim S_1 + S_2, \quad (6.6)$$

where

$$\begin{aligned}
 S_1 &= \sum_{n=1}^{\infty} \exp \left\{ \ell n^b + \beta (\log 3) n^{1-a} + (\ell - \lambda \beta + c \beta^{\frac{1}{1-a}}) n - \eta \beta n^{1-a+b} \right\}, \\
 S_2 &= \sum_{n=1}^{\infty} \exp \left\{ -\ell n^b + n \ell - \lambda \beta n + \left(\frac{t}{2} \mathcal{E} + \varepsilon \right) \beta^{\frac{1}{1-a}} n \right\}.
 \end{aligned}$$

Since $1 - a + b > 1$, the term $e^{-\eta\beta n^{1-a+b}}$ is dominant, and hence, S_1 is finite for every $\lambda, \beta > 0$. To ensure the convergence of S_2 , we choose λ such that

$$\lambda > \ell\beta^{-1} + \left(\frac{t}{2}\mathcal{E} + \varepsilon\right)\beta^{\frac{a}{1-a}}. \quad (6.7)$$

It follows that the series on the right hand side of (6.6) is finite. By Borel-Cantelli lemma, we have almost surely

$$\limsup_{n \rightarrow \infty} n^{-a} \sup_{x \in K, |y| \leq e^n} \log \mathcal{K}(x, y) \leq \lambda.$$

Evidently, the best choice for λ is

$$\begin{aligned} \lambda_0 &:= \inf_{\varepsilon > 0, \beta > 0} \left\{ \ell\beta^{-1} + \left(\frac{t}{2}\mathcal{E} + \varepsilon\right)\beta^{\frac{a}{1-a}} \right\} \\ &= \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{t\mathcal{E}}{2 - \bar{\alpha}} \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}}, \end{aligned} \quad (6.8)$$

which yields (6.3). \square

Remark 6.2 Using Proposition 5.6 and analogous arguments in Theorem 6.1, we can show that

$$\begin{aligned} &\limsup_{R \rightarrow \infty} (\log R)^{-\frac{2}{4-\bar{\alpha}}} \sup_{x \in K, \varepsilon \in (0, 1], |y| \leq R} \left(\log \mathcal{Z}_\varepsilon(x; t, y) + \frac{|y - x|^2}{2t} \right) \\ &\leq \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4-\bar{\alpha}}} \left(\frac{\mathcal{E}}{2 - \bar{\alpha}} t \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}}. \end{aligned} \quad (6.9)$$

We omit the details.

6.2 The lower bound

We now focus on the lower bound of (1.15) and (1.26). To start, we explain an issue of using the localization procedure as in [3, 7]. In these papers, a localized version of the Eq. (1.1) is introduced, i.e.

$$U^\beta(t, x) = 1 + \int_0^t \int_{|y-x| \leq \beta\sqrt{t}} p_{t-s}(x - y) U^\beta(s, y) W(ds, dy), \quad (6.10)$$

for some $\beta > 0$. For fixed t and β sufficiently large, $\sup_{|x| \leq R} U^\beta(t, x)$ gives a good approximation for $\sup_{|x| \leq R} u(t, x)$ as $R \rightarrow \infty$. In our situation, suppose for instance

that $u_0 = \delta(\cdot - x_0)$, the random field $\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)}$ satisfies the equation

$$\frac{\mathcal{Z}(x_0; t, x)}{p_t(x - x_0)} = 1 + \int_0^t \int_{\mathbb{R}^\ell} p_{\frac{s(t-s)}{t}} \left(y - x_0 - \frac{s}{t}(x - x_0) \right) \frac{\mathcal{Z}(x_0; s, y)}{p_s(y - x_0)} W(ds, dy). \quad (6.11)$$

Since the kernel $p_{\frac{s(t-s)}{t}} \left(y - x_0 - \frac{s}{t}(x - x_0) \right)$ now involves s and t with s moving from 0 to t , the mass concentration of the stochastic integration on the right-hand side of (6.11) varies and depends on s . We are not able to find a fixed localized integration domain similar as $\{y : |y - x| \leq \beta\sqrt{t}\}$. To get around this difficulty, we propose an alternative result (Theorem 1.5) which is about the regularized version of \mathcal{Z} , i.e., \mathcal{Z}_ε . To handle the spatial asymptotic of \mathcal{Z}_ε , we rely on the Feynman–Kac representation (4.2) and adopt an argument developed by Xia Chen in [3] with an additional scaling procedure.

Hereafter, t and ε are fixed positive constants, n is the driving parameter which tends to infinity,

$$\varepsilon_n = \begin{cases} 0 & \text{if (H.1) holds} \\ \varepsilon \left(\frac{t}{n}\right)^a & \text{if (H.2) holds.} \end{cases} \quad (6.12)$$

Let y_1, \dots, y_N be N points in $B(0, e^n)$ and d be a positive number such that

$$N \lesssim e^{\ell n} \quad \text{and} \quad |y_j - y_k| \geq d \quad \forall j \neq k. \quad (6.13)$$

Under (H.1), d is chosen to be sufficiently large, depending on the shape of γ , while under (H.2), we can simply choose $d = 1$. See Lemma 6.4 below for more details.

Theorem 6.3 For every $x_0 \in \mathbb{R}^\ell$

$$\liminf_{n \rightarrow \infty} n^{-a} \sup_{|y| \leq e^n} \sup_{\varepsilon \in (0, 1)} \log \frac{\mathcal{Z}_\varepsilon(x_0; t, y)}{p_t(y - x_0)} \geq \frac{4 - \bar{\alpha}}{2} \ell^{\frac{2}{4 - \bar{\alpha}}} \left(\frac{\mathcal{E}}{2 - \bar{\alpha}} t \right)^{\frac{2 - \bar{\alpha}}{4 - \bar{\alpha}}} \quad (6.14)$$

Proof Step 1: Let $m = m_n$ be a natural number such that

$$\lim_{n \rightarrow \infty} \frac{n^{1-a}}{m_n} \rightarrow 0. \quad (6.15)$$

Under hypothesis (H.1), for each j , we define the stopping time

$$\tau^j = \inf \left\{ s \geq 0 : |B^j(s)| \geq r_0 \right\} \quad (6.16)$$

where $r_0 > 0$ is chosen so that

$$\inf_{|x| < 2r_0} \gamma(x) > 0. \quad (6.17)$$

Such a constant always exists since γ is continuous and $\gamma(0) > 0$. Under hypothesis (H.2), the stopping time depends on n and an arbitrary domain. More precisely, let

D be an open bounded ball in \mathbb{R}^ℓ which contains 0. For each j , $\tau^j = \tau_n^j(D)$ denotes the stopping time

$$\tau_n^j(D) = \inf \left\{ s \geq 0 : B^j(s) \notin \left(\frac{t}{n} \right)^{\frac{a}{2}} D \right\}. \quad (6.18)$$

As previously, we denote

$$\mathcal{K}_{\varepsilon_n}(x, y) = \frac{Z_{\varepsilon_n}(x; t, y)}{p_t(y - x)},$$

omitting the dependence on t . We note that from (4.2)

$$\begin{aligned} & (\mathcal{K}_{\varepsilon_n}(x_0, y))^m \\ &= \mathbb{E}_B \exp \left(\sum_{j=1}^m \int_0^t \int_{\mathbb{R}^\ell} \delta \left(B_{0,t}^j(t-s) + \frac{t-s}{t} x_0 + \frac{s}{t} y - z \right) W_{\varepsilon_n}(ds, dz) - \frac{tm}{2} \gamma_{\varepsilon_n}(0) \right) \\ &= e^{-\frac{tm}{2} \gamma_{\varepsilon_n}(0)} \mathbb{E}_B e^{\xi_m(x_0, y)}, \end{aligned}$$

where

$$\xi_m(x_0, y) = \sum_{j=1}^m \int_0^t \int_{\mathbb{R}^\ell} \delta \left(B_{0,t}^j(t-s) + \frac{t-s}{t} x_0 + \frac{s}{t} y - z \right) W_{\varepsilon_n}(ds, dz). \quad (6.19)$$

Conditioning on B , the variance of $\xi_m(x_0, y)$ is given by

$$S_m^2 = \mathbb{E}_B(\xi_m(x_0, y)^2) = \sum_{j,k=1}^m \int_0^t \gamma_{\varepsilon_n}(B_{0,t}^j(s) - B_{0,t}^k(s)) ds.$$

For every $\lambda > 0$, it is evident that

$$\begin{aligned} \mathbb{E}_B e^{\xi_m(x_0, y)} &\geq \mathbb{E}_B \left\{ e^{\lambda \sqrt{n} S_m(t)}; \xi_m(x_0, y) \geq \lambda \sqrt{n} S_m(t), \min_{1 \leq k \leq m} \tau^k \geq t \right\} \\ &= [\mathbb{E}_B Z_m(n)] \eta_n(x_0, y), \end{aligned}$$

where we have put

$$Z_m(n) = e^{\lambda \sqrt{n} S_m(t)} \mathbf{1}_{\{\min_{1 \leq j \leq m} \tau_n^j(D) \geq t\}}, \quad (6.20)$$

and

$$\eta_n(x_0, y) := [\mathbb{E}_B Z_m(n)]^{-1} \mathbb{E}_B \left(Z_m(n) \mathbf{1}_{\{\xi_m(x_0, y) \geq \lambda \sqrt{n} S_m(t)\}} \right). \quad (6.21)$$

Combining all previous estimates, we arrive at an important inequality

$$\mathcal{K}_{\varepsilon_n}(x_0, y) \geq e^{-\frac{t}{2} \gamma_{\varepsilon_n}(0)} [\mathbb{E}_B Z_m(n)]^{\frac{1}{m}} [\eta_n(x_0, y)]^{\frac{1}{m}}. \quad (6.22)$$

It follows that

$$\begin{aligned} \sup_{j=1,\dots,N} \mathcal{K}_{\varepsilon_n}(x_0, y_j) &\geq N^{-\frac{1}{m}} \left(\sum_{j=1}^N [\mathcal{K}_{\varepsilon_n}(x_0, y_j)]^m \right)^{\frac{1}{m}} \\ &\geq N^{-\frac{1}{m}} e^{-\frac{t}{2}\gamma_{\varepsilon_n}(0)} [\mathbb{E}_B Z_m(n)]^{\frac{1}{m}} \left(\sum_{j=1}^N \eta_n(x_0, y_j) \right)^{\frac{1}{m}}. \end{aligned}$$

We put

$$\eta_n^c(x_0) = [\mathbb{E}_B Z_m(n)]^{-1} \mathbb{E}_B \left(Z_m(n) \mathbf{1}_{\{\max_{j=1,\dots,N} \xi_m(x_0, y_j) < \lambda \sqrt{n} S_m(t)\}} \right). \quad (6.23)$$

Applying the estimate

$$\sum_{j=1}^N \eta_n(x_0, y_j) \geq 1 - \eta_n^c(x_0),$$

we obtain

$$\sup_{j=1,\dots,N} \mathcal{K}_{\varepsilon_n}(x_0, y_j) \geq N^{-\frac{1}{m}} e^{-\frac{t}{2}\gamma_{\varepsilon_n}(0)} [\mathbb{E}_B Z_m(n)]^{\frac{1}{m}} [1 - \eta_n^c(x_0)]^{\frac{1}{m}} \quad (6.24)$$

Noting that $N^{-\frac{1}{m}} \lesssim e^{\ell \frac{n}{m}}$ and by (1.24), $\gamma_{\varepsilon_n}(0) = \varepsilon_n^{-\frac{\alpha}{2}} \gamma_1(0) \lesssim n^{\frac{\alpha}{2}a}$, we see that

$$\lim_{n \rightarrow \infty} n^{-a} \log \left(N^{-\frac{1}{m}} e^{-\frac{t}{2}\gamma_{\varepsilon_n}(0)} \right) = 0. \quad (6.25)$$

In other words, the factor $N^{-\frac{1}{m}} e^{-\frac{t}{2}\gamma_{\varepsilon_n}(0)}$ in (6.24) is negligible. In addition, we claim that for every $\lambda \in (0, \sqrt{2\ell})$ and every $x \in \mathbb{R}^\ell$

$$\lim_{n \rightarrow \infty} \eta_n^c(x_0) = 0 \quad \text{a.s.} \quad (6.26)$$

We postpone the proof of this claim till Lemma 6.4 below. It follows that

$$\liminf_{n \rightarrow \infty} n^{-a} \log \max_{j=1,\dots,N} \mathcal{K}_{\varepsilon_n}(x_0, y_j) \geq \liminf_{n \rightarrow \infty} n^{-a} m^{-1} \log \mathbb{E}_B Z_m(n). \quad (6.27)$$

Step 2: We will show that

$$\liminf_{\varepsilon \downarrow 0, D \uparrow \mathbb{R}^\ell} \liminf_{n \rightarrow \infty} n^{-a} m^{-1} \log \mathbb{E}_B Z_m(n) \geq \frac{4 - \bar{\alpha}}{4} \lambda^{\frac{4}{4-\bar{\alpha}}} \left(\frac{2t\mathcal{E}}{2 - \bar{\alpha}} \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}}. \quad (6.28)$$

We consider first the hypothesis (H.1). Since γ is continuous, for any $\varepsilon > 0$, there is δ such that whenever $|z| \leq \delta \wedge r_0$, $\gamma(z) \geq \gamma(0) - \varepsilon$. Hence,

$$\mathbb{E}_B Z_m(n) \geq \exp \left\{ \lambda \sqrt{n} [m(m-1)t(\gamma(0) - \varepsilon)]^{1/2} \right\} \mathbb{P} \left(\sup_{0 \leq s \leq t} |B_{0,t}^j(s)| \leq \delta \wedge r_0 \right)^m.$$

Since as $n \rightarrow \infty$, $m \rightarrow \infty$ too, we have

$$\liminf_{n \rightarrow \infty} m^{-1} n^{-1/2} \log \mathbb{E} Z_m(n) \geq \lambda \sqrt{t(\gamma(0) - \varepsilon)},$$

which proves (6.28) under (H.1).

Assume now that (H.2) holds. We put $t_n = t^{1-a} n^a$ so that $\varepsilon_n = \varepsilon \frac{t}{t_n}$. The Brownian motion scaling and the relation (1.24) yield

$$\begin{aligned} \int_0^t \gamma_{\varepsilon_n} (B_{0,t}^j(s) - B_{0,t}^k(s)) ds &= \frac{t}{t_n} \int_0^{t_n} \gamma_{\varepsilon \frac{t}{t_n}} \left(B_{0,t}^j \left(s \frac{t}{t_n} \right) - B_{0,t}^k \left(s \frac{t}{t_n} \right) \right) ds \\ &\stackrel{\text{law}}{=} \frac{t}{t_n} \int_0^{t_n} \gamma_{\varepsilon \frac{t}{t_n}} \left(\sqrt{\frac{t}{t_n}} (B_{0,t_n}^j(s) - B_{0,t_n}^k(s)) \right) ds \\ &= \left(\frac{t}{t_n} \right)^{1-\frac{\alpha}{2}} \int_0^{t_n} \gamma_{\varepsilon} (B_{0,t_n}^j(s) - B_{0,t_n}^k(s)) ds. \end{aligned}$$

It follows that

$$\mathbb{E} Z_m(n) = \mathbb{E}_B \left[\exp \left\{ \lambda \left(t_n \sum_{j,k=1}^m \int_0^{t_n} \gamma_{\varepsilon} (B_{0,t_n}^j(s) - B_{0,t_n}^k(s)) ds \right)^{\frac{1}{2}} \right\}; \min_{1 \leq j \leq m} \tau_D^j \geq t_n \right],$$

where

$$\tau_D^j = \inf \left\{ s \geq 0 : B^j(s) \notin D \right\}.$$

Let K_{ε} be the function defined by

$$K_{\varepsilon}(x) = (2\pi)^{-\ell} \int_{\mathbb{R}^{\ell}} e^{i\xi \cdot x - \frac{\varepsilon}{2} |\xi|^2} \sqrt{\mu(\xi)} d\xi$$

so that

$$\gamma_{\varepsilon}(x) = \int_{\mathbb{R}^{\ell}} K_{\varepsilon}(y) K_{\varepsilon}(x - y) dy. \quad (6.29)$$

Hence, we can write

$$\left(t_n \sum_{j,k=1}^m \int_0^{t_n} \gamma_{\varepsilon} (B_{0,t_n}^j(s) - B_{0,t_n}^k(s)) ds \right)^{\frac{1}{2}} = \left(t_n \int_0^{t_n} \int_{\mathbb{R}^{\ell}} \left| \sum_{j=1}^m K_{\varepsilon}(x - B_{0,t_n}^j(s)) \right|^2 dx ds \right)^{\frac{1}{2}}.$$

Let \mathcal{D} be the set of compactly supported continuous functions on \mathbb{R}^ℓ with unit $L^2(\mathbb{R}^\ell)$ -norm. For every $f \in \mathcal{D}$, applying Cauchy–Schwarz inequality, we see that the right-hand side in the equation above is at least

$$\sum_{j=1}^m \int_0^{t_n} \int_{\mathbb{R}^\ell} f(x) K_\varepsilon(x - B_{0,t_n}^j(s)) dx ds = \sum_{j=1}^m \int_0^{t_n} \bar{f}_\varepsilon(B_{0,t_n}^j(s)) ds,$$

where we have set

$$\bar{f}_\varepsilon(x) = \int_{\mathbb{R}^\ell} f(y) K_\varepsilon(y - x) dy.$$

Using independence of Brownian motions, we obtain

$$\mathbb{E}_B Z_m(n) \geq \left(\mathbb{E}_B \left[\exp \left\{ \lambda \int_0^{t_n} \bar{f}_\varepsilon(B_{0,t_n}(s)) ds \right\}; \tau_D \geq t_n \right] \right)^m,$$

where $\tau_D := \inf\{s \geq 0 : B(s) \notin D\}$. Applying Lemma 3.5 we obtain

$$\liminf_{n \rightarrow \infty} \frac{1}{m t_n} \log \mathbb{E}_B Z_m(n) \geq \sup_{g \in \mathcal{G}_D} \left\{ \lambda \int_D \bar{f}_\varepsilon(x) g^2(x) dx - \frac{1}{2} \int_D |\nabla g(x)|^2 dx \right\}.$$

We now let $D \uparrow \mathbb{R}^\ell$ to get

$$\liminf_{D \uparrow \mathbb{R}^\ell} \liminf_{n \rightarrow \infty} \frac{1}{m n^a} \log \mathbb{E}_B Z_m(n) \geq t^{1-a} \sup_{g \in \mathcal{G}} \left\{ \lambda \int_{\mathbb{R}^\ell} \bar{f}_\varepsilon(x) g^2(x) dx - \frac{1}{2} \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right\}.$$

We now link the variation on the right-hand side with $\mathcal{M}(\gamma)$ (cf. (3.4)) by observing that

$$\sup_{f \in \mathcal{D}} \sup_{g \in \mathcal{G}} \left\{ \lambda \int_{\mathbb{R}^\ell} \bar{f}_\varepsilon(x) g^2(x) dx - \frac{1}{2} \int_{\mathbb{R}^\ell} |\nabla g(x)|^2 dx \right\} = \mathcal{M}(\lambda^2 \gamma_\varepsilon). \quad (6.30)$$

Indeed, for each fixed $g \in \mathcal{G}$, applying Fubini's theorem, Hahn-Banach theorem and (6.29), we have

$$\begin{aligned} \sup_{f \in \mathcal{D}} \int_{\mathbb{R}^\ell} \bar{f}_\varepsilon(x) g^2(x) dx &= \sup_{f \in \mathcal{D}} \int_{\mathbb{R}^\ell} f(y) \int_{\mathbb{R}^\ell} K_\varepsilon(y - x) g^2(x) dx dy \\ &= \left(\int_{\mathbb{R}^\ell} \left| \int_{\mathbb{R}^\ell} K_\varepsilon(y - x) g^2(x) dx \right|^2 dy \right)^{\frac{1}{2}} \\ &= \left(\int_{\mathbb{R}^\ell} \int_{\mathbb{R}^\ell} \gamma_\varepsilon(x - y) g^2(x) g^2(y) dx dy \right)^{\frac{1}{2}}. \end{aligned}$$

This leads us the identity (6.30). We can send $\varepsilon \downarrow 0$, applying Lemma 3.2 and Proposition 3.3, to obtain (6.28) under hypothesis (H.2).

Step 3: Combining the inequalities (6.27) and (6.28) together, we have for every $\lambda \in (0, \sqrt{2\ell})$

$$\liminf_{n \rightarrow \infty} \sup_{j=1, \dots, N} \mathcal{K}_{\varepsilon_n}(x_0, y_j) \geq \frac{4 - \bar{\alpha}}{4} \lambda^{\frac{4}{4-\bar{\alpha}}} \left(\frac{2t\mathcal{E}}{2 - \bar{\alpha}} \right)^{\frac{2-\bar{\alpha}}{4-\bar{\alpha}}}.$$

Finally we let $\lambda \rightarrow \sqrt{2\ell}^-$ to conclude the proof. \square

We now provide the proof of (6.26).

Lemma 6.4 *For every $\lambda \in (0, \sqrt{2\ell})$, we have*

$$\lim_{n \rightarrow \infty} \eta_n^c(x_0) = 0 \quad \text{a.s.} \quad (6.31)$$

where we recall η_n^c is defined in (6.23).

Proof Assuming first that (H.1) holds. We recall that $\varepsilon_n = 0$ in this case so that $\gamma_{\varepsilon_n} = \gamma$. Let \mathcal{B} be the σ -field generated by the Brownian motions $\{B^j\}_{1 \leq j \leq m}$. First we will show that for any $0 < \rho < \frac{1}{2}$, we can find $d > 0$ sufficiently large so that on the event $\{\min_{1 \leq j \leq m} \tau^j \geq t\}$, for every $z, z' \in B(0, e^n)$ with $|z - z'| \geq d$.

$$\text{Cov} \left(\xi_m(x_0, z), \xi_m(x_0, z') \middle| \mathcal{B} \right) \leq \rho S_m^2. \quad (6.32)$$

We recall that d and τ^j are defined in (6.13) and (6.16) respectively. We choose and fix $\varkappa \in (0, 1)$ such that

$$\varkappa \gamma(0) \leq \frac{1}{2} \rho \inf_{|x| \leq 2r_0} \gamma(x). \quad (6.33)$$

Note that on the event $\{\min_{1 \leq j \leq m} \tau^j \geq t\}$, we have $\sup_{s \leq t, j \leq m} |B_{0,t}^j(s)| \leq r_0$. Then for every $j, k \leq m$,

$$\begin{aligned} \int_0^{\varkappa t} \gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) + \frac{s}{t}(z - z') \right) ds &\leq \varkappa t \gamma(0) \\ &\leq \frac{\rho}{2} \int_0^t \gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) \right) ds. \end{aligned}$$

In addition, from (1.3) and Riemann–Lebesgue lemma, $\lim_{x \rightarrow \infty} \gamma(x) = 0$. Hence, when $s \in [\varkappa t, t]$, we can choose d large enough such that whenever $|y| \leq 2r_0$ and $|z - z'| \geq d$

$$\gamma \left(y + \frac{s}{t}(z - z') \right) \leq \frac{\rho}{2} \gamma(y).$$

In particular, for every $|z - z'| \geq d$ we have

$$\gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) + \frac{s}{t}(z - z') \right) \leq \frac{\rho}{2} \gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) \right). \quad (6.34)$$

It follows that

$$\begin{aligned} & \text{Cov} \left(\xi_m(t, z), \xi_m(t, z') \middle| \mathcal{B} \right) \\ &= \sum_{j,k=1}^m \int_0^t \gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) + \frac{s}{t}(z-z') \right) ds \\ &\leq \rho \sum_{j,k=1}^m \int_0^t \gamma \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) \right) ds, \end{aligned}$$

which verifies (6.32).

Since $\lambda < \sqrt{2\ell}$, we can choose $\kappa, \rho \in (0, \frac{1}{2})$ sufficiently small so

$$\frac{(1+2\rho)(\lambda+\kappa)^2}{2} < \ell \quad \text{and} \quad \frac{\kappa^2}{4\rho} > \ell + 1. \quad (6.35)$$

Let us now recall Lemma 4.2 in [2]. For a mean zero n -dimensional Gaussian vector (ξ_1, \dots, ξ_n) with identically distributed components,

$$\max_{i \neq j} \frac{|\text{Cov}(\xi_i, \xi_j)|}{\text{Var}(\xi_1)} \leq \rho < \frac{1}{2} \quad (6.36)$$

and for any $A, B > 0$, we have

$$\mathbb{P} \left\{ \max_{k \leq n} \xi_k \leq A \right\} \leq \left(\mathbb{P} \left\{ \xi_1 \leq \sqrt{1+2\rho}(A+B) \right\} \right)^n + \mathbb{P} \left\{ U \geq B/\sqrt{2\rho \text{Var}(\xi_1)} \right\} \quad (6.37)$$

where U is a standard normal random variable. Applying this inequality conditionally with $A = \lambda S_m(t)\sqrt{n}$ and $B = \kappa S_m\sqrt{n}$, we have for sufficiently large n ,

$$\begin{aligned} & \mathbb{P} \left\{ \max_{j=1, \dots, N} \xi_m(x_0, y_j) < \lambda\sqrt{n}S_m \middle| \mathcal{B} \right\} \\ & \leq \left(\mathbb{P} \left\{ U \leq \sqrt{1+2\rho}(\lambda+\kappa)\sqrt{n} \right\} \right)^N + \mathbb{P} \left\{ U \geq \frac{\kappa}{\sqrt{2\rho}}\sqrt{n} \right\} \\ & \leq \exp \left\{ -(1+o(1))Ce^{vn} \right\} + e^{-(\ell+1)n} \leq Ce^{-(\ell+1)n}, \end{aligned}$$

where $v > 0$ is independent of n . Now for any $\theta > 0$, this yields

$$\begin{aligned} \mathbb{P}(\eta_n^c(x_0) \geq \theta) &\leq \theta^{-1} \mathbb{E} \eta_n^c(x_0) \\ &= (\theta \mathbb{E} Z_m(n))^{-1} \mathbb{E} \left[Z_m(n) \mathbb{P} \left\{ \max_{j=1, \dots, N} \xi_m(x_0, y_j) < \lambda\sqrt{n}S_m \middle| \mathcal{B} \right\} \right] \\ &\lesssim Ce^{-(\ell+1)n}. \end{aligned}$$

An application of Borel-Cantelli lemma yields (6.31) under hypothesis (H.1).

We now consider the hypothesis (H.2). The argument is similar to the previous case. There is, however, an additional scaling procedure. Recall that \mathcal{B} is the σ -field generated by the Brownian motions $\{B^j\}_{1 \leq j \leq m}$. We choose $d = 1$. It suffices to prove (6.32) on the event $\{\min_{0 \leq j \leq m} \tau^j \geq t\}$, for any $|z - z'| \geq 1$. Indeed, we have

$$\text{Cov} \left(\xi_m(x_0, z), \xi_m(x_0, z') \middle| \mathcal{B} \right) = \sum_{j,k=1}^m \int_0^t \gamma_{\varepsilon_n} \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) + \frac{s}{t}(z - z') \right) ds.$$

For every $j, k \leq m$, using the scaling relation (1.24), we can write

$$\begin{aligned} & \gamma_{\varepsilon_n} \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) + \frac{s}{t}(z - z') \right) \\ &= \varepsilon_n^{-\frac{\alpha}{2}} \gamma_1 \left(\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) + \varepsilon_n^{-\frac{1}{2}} \frac{s}{t}(z - z') \right). \end{aligned}$$

We now choose and fix $\theta > 0$ such that

$$\theta \leq \frac{\rho}{2\gamma_1(0)} \inf_{x \in \varepsilon^{-1/2}D} \gamma_1(x), \quad (6.38)$$

this is always possible since $\gamma_1 = p_2 * \gamma$ is a strictly positive function. It follows that

$$\begin{aligned} & \varepsilon_n^{-\frac{\alpha}{2}} \int_0^{\theta t} \gamma_1 \left(\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) + \varepsilon_n^{-\frac{1}{2}} \frac{s}{t}(z - z') \right) ds \\ & \leq \varepsilon_n^{-\frac{\alpha}{2}} \theta t \gamma_1(0) \\ & \leq \frac{\rho}{2} \varepsilon_n^{-\frac{\alpha}{2}} \int_0^t \gamma_1 \left(\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) \right) ds \\ & = \frac{\rho}{2} \int_0^t \gamma_{\varepsilon_n} \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) \right) ds. \end{aligned}$$

In addition, on the event $\{\min_{0 \leq j \leq m} \tau^j \geq t\}$, $\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s))$ belongs to $2\varepsilon^{-\frac{1}{2}}D$ for all $s \in [0, t]$. Hence, for every $s \in [\theta t, t]$ and $|z - z'| \geq 1$, we have

$$\left| \varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) + \varepsilon_n^{-\frac{1}{2}} \frac{s}{t}(z - z') \right| \geq \theta \varepsilon_n^{-\frac{1}{2}} - 2\varepsilon^{-\frac{1}{2}} \text{diag}(D).$$

We note that from Riemann–Lebesgue lemma, $\lim_{x \rightarrow \infty} \gamma_1(x) = 0$. Hence, whenever n is sufficiently large,

$$\gamma_1(y) \leq \frac{\rho}{2} \inf_{x \in \varepsilon^{-1/2}D} \gamma_1(x)$$

for all $|y| \geq \theta \varepsilon_n^{-\frac{1}{2}} - 2\varepsilon^{-\frac{1}{2}} \text{diag}(D)$. It follows that for every z, z' with $|z - z'| \geq 1$,

$$\begin{aligned} & \varepsilon_n^{-\frac{\alpha}{2}} \int_{\theta t}^t \gamma_1 \left(\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) + \varepsilon_n^{-\frac{1}{2}} \frac{s}{t} (z - z') \right) ds \\ & \leq \varepsilon_n^{-\frac{\alpha}{2}} \frac{\rho}{2} \int_{\theta t}^t \gamma_1 \left(\varepsilon_n^{-\frac{1}{2}} (B_{0,t}^j(t-s) - B_{0,t}^k(t-s)) \right) ds \\ & \leq \frac{\rho}{2} \int_0^t \gamma_{\varepsilon_n} \left(B_{0,t}^j(t-s) - B_{0,t}^k(t-s) \right) ds. \end{aligned}$$

Upon combining these estimates, we arrive at (6.32), which in turn, implies (6.31). \square

6.3 Proofs

Theorems 1.3, 1.4 and 1.5 follow from the asymptotic results from the previous two subsections. Indeed, Theorem 1.3 follows by combining the upper bound in Theorem 6.1 and the lower bound in Theorem 6.3. To obtain Theorem 1.4, we first observe that from (4.1),

$$\frac{u(t, y)}{p_t * u_0(y)} \leq \sup_{x \in \text{supp } u_0} \frac{\mathcal{Z}(x; t, y)}{p_t(x - y)}. \quad (6.39)$$

Then, an application of Theorem 6.1 yields the result. For Theorem 1.5, the upper bound of (1.25) follows from Remark 6.2 and the bound (6.39) with u, \mathcal{Z} replaced respectively by $u_\varepsilon, \mathcal{Z}_\varepsilon$, together with the obvious fact that $\mathcal{E}_H(\gamma_\varepsilon) \leq \mathcal{E}_H(\gamma)$, see (3.3). The lower bound of (1.26) is immediate from Theorem 6.3.

Acknowledgements The project was initiated while both authors were visiting the Mathematical Sciences Research Institute in Berkeley, California, during the Fall 2015 semester. The first named author thanks Professor Davar Khoshnevisan for stimulating discussions and encouragement. The second named author thanks PIMS for its support through the Postdoctoral Training Centre in Stochastics. Both authors thank Professor Yaozhong Hu and Professor David Nualart for support and encouragement. We also thank the referee for a thorough report and numerous comments which improved the presentation of the paper.
