eFigure 1: Meta-analysis of the effect of blood pressure-lowering treatment on systolic blood pressure stratified by mean of baseline systolic blood pressure

Mean differences between the change in systolic blood pressure in the intervention group versus the control group are displayed for each trial and each strata of mean baseline systolic blood pressure aggregated at trial-level. Summary measures were calculated using random effects models with REML estimators. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. Only studies that compared active treatment with placebo were included. BP diff, difference between achieved and baseline systolic blood pressure; SBP, systolic blood pressure

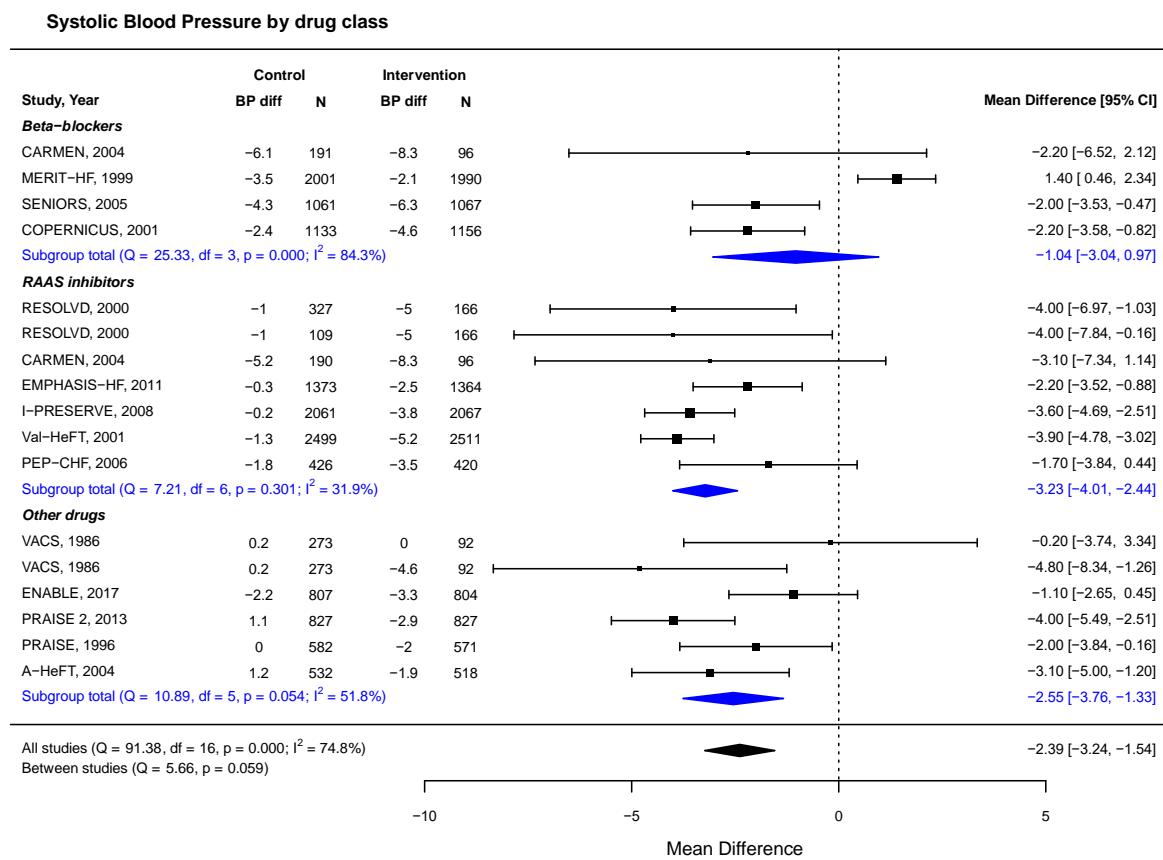

eFigure2: Meta-analysis of the effect of blood pressure-lowering treatment on systolic blood pressure stratified by drug class excluding the MERIT-HF trial

Systolic Blood Pressure by drug class

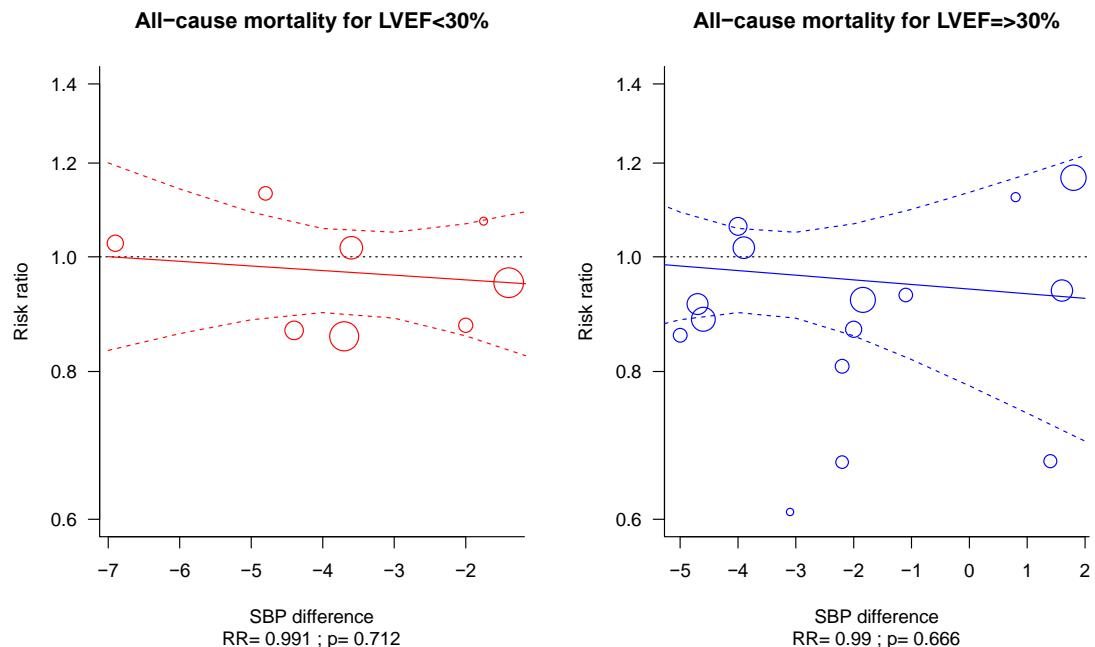

Mean differences between the change in systolic blood pressure in the intervention group versus the control group are displayed for each drug class. The outlier trial MERIT-HF was excluded from the beta-blocker subgroup to assess the impact of this trial on the subgroup estimate. Summary measures were calculated using random effects models with REML estimators. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. Other drugs include calcium-channel blockers, alpha-blockers, and hydralazine-isosorbide dinitrate. Only studies that compared active treatment with placebo were included. SBP, systolic blood pressure; RAAS, renin-angiotensin-aldosterone system

eFigure 3: Meta-analysis of the effect of blood pressure-lowering treatment on systolic blood pressure stratified by drug class

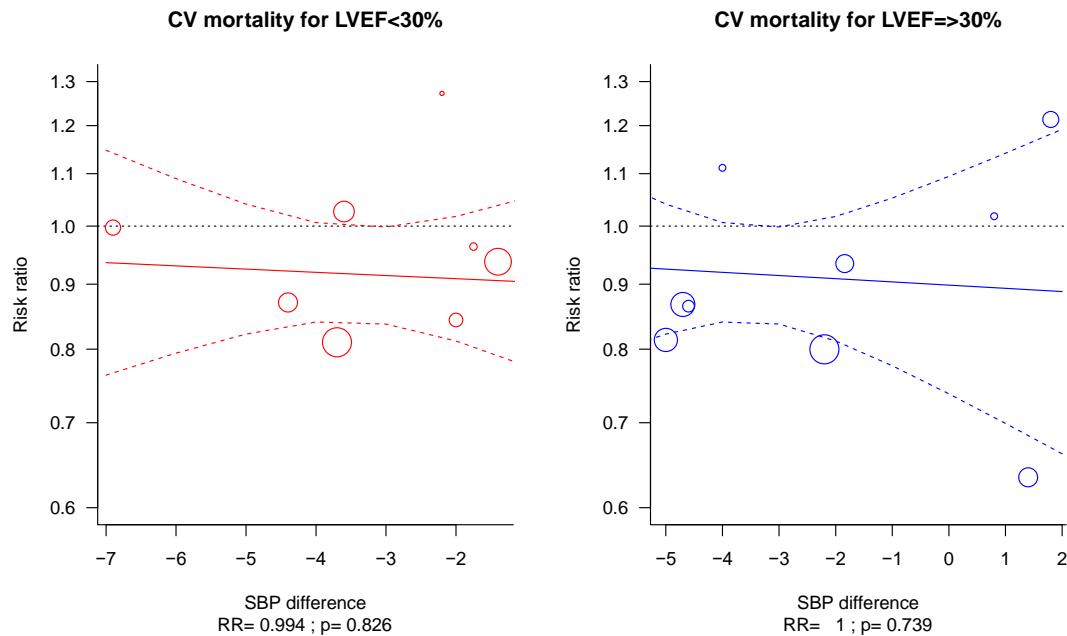

Mean differences between the change in systolic blood pressure in the intervention group versus the control group are displayed for each trial and each drug class. Summary measures were calculated using random effects models with REML estimators. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. Other drugs include calcium-channel blockers, alpha-blockers, and hydralazine-isosorbide dinitrate. Only studies that compared active treatment with placebo were included. BP diff, difference between achieved and baseline systolic blood pressure; SBP, systolic blood pressure; RAAS, renin-angiotensin-aldosterone system

eFigure 4: Meta-regression of risk ratio for all-cause mortality according to the difference in systolic blood pressure between study groups stratified by left-ventricular ejection fraction

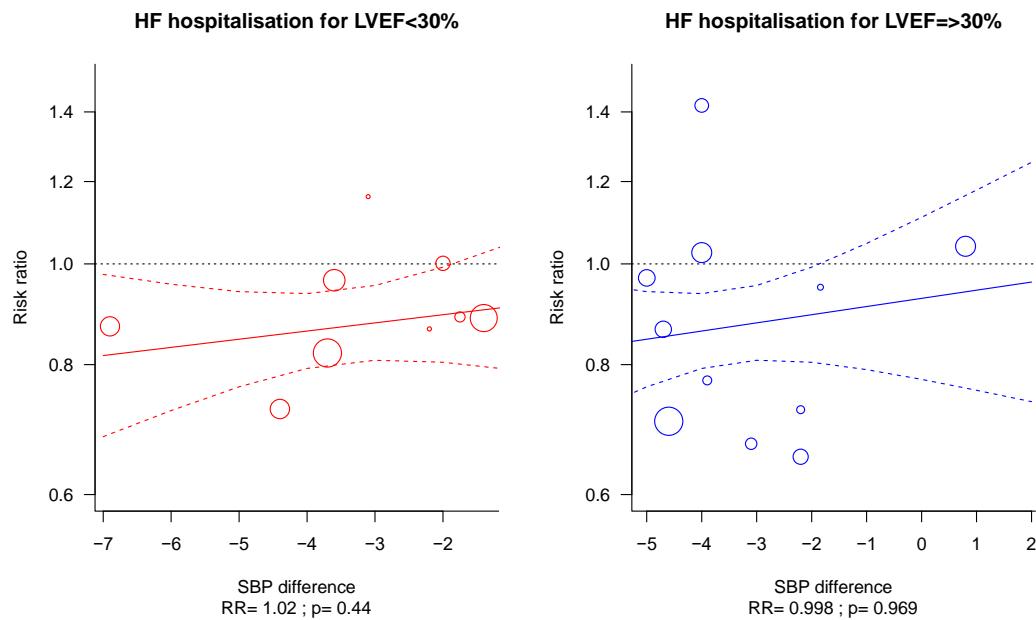

Risk ratios for all-cause mortality were regressed against the mean difference in systolic blood pressure change between the intervention and control groups in each trial and stratified by left-ventricular ejection fraction using a 30% cut-off. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. SBP, systolic blood pressure

eFigure 5: Meta-regression of risk ratio for cardiovascular mortality according to the difference in systolic blood pressure between study groups stratified by left-ventricular ejection fraction

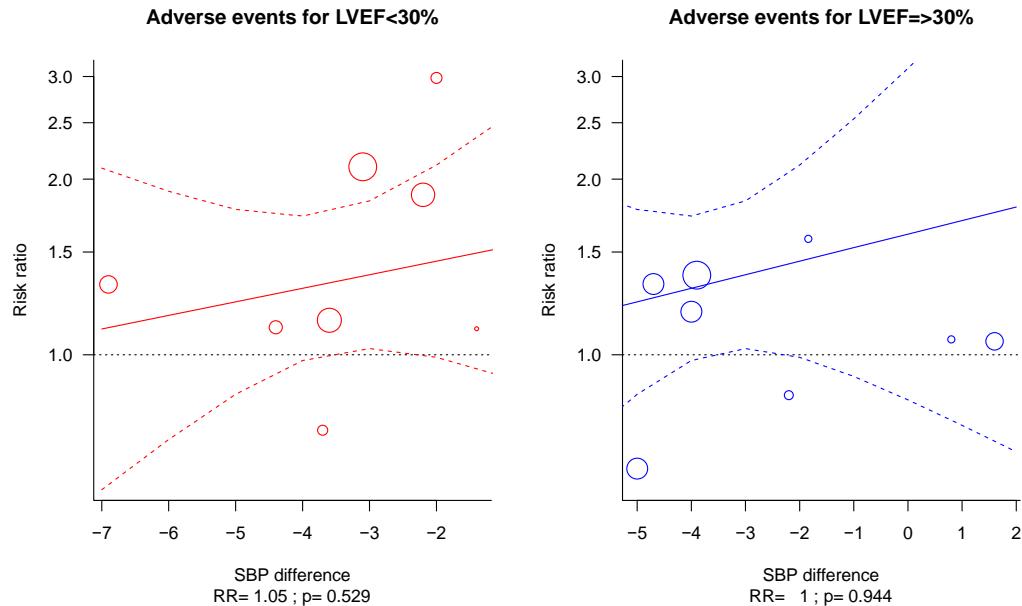

Risk ratios for cardiovascular (CV) mortality were regressed against the mean difference in systolic blood pressure change between the intervention and control groups in each trial and stratified by left-ventricular ejection fraction using a 30% cut-off. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. SBP, systolic blood pressure

eFigure 6: Meta-regression of risk ratio for heart failure hospitalisation according to the difference in systolic blood pressure between study groups stratified by left-ventricular ejection fraction

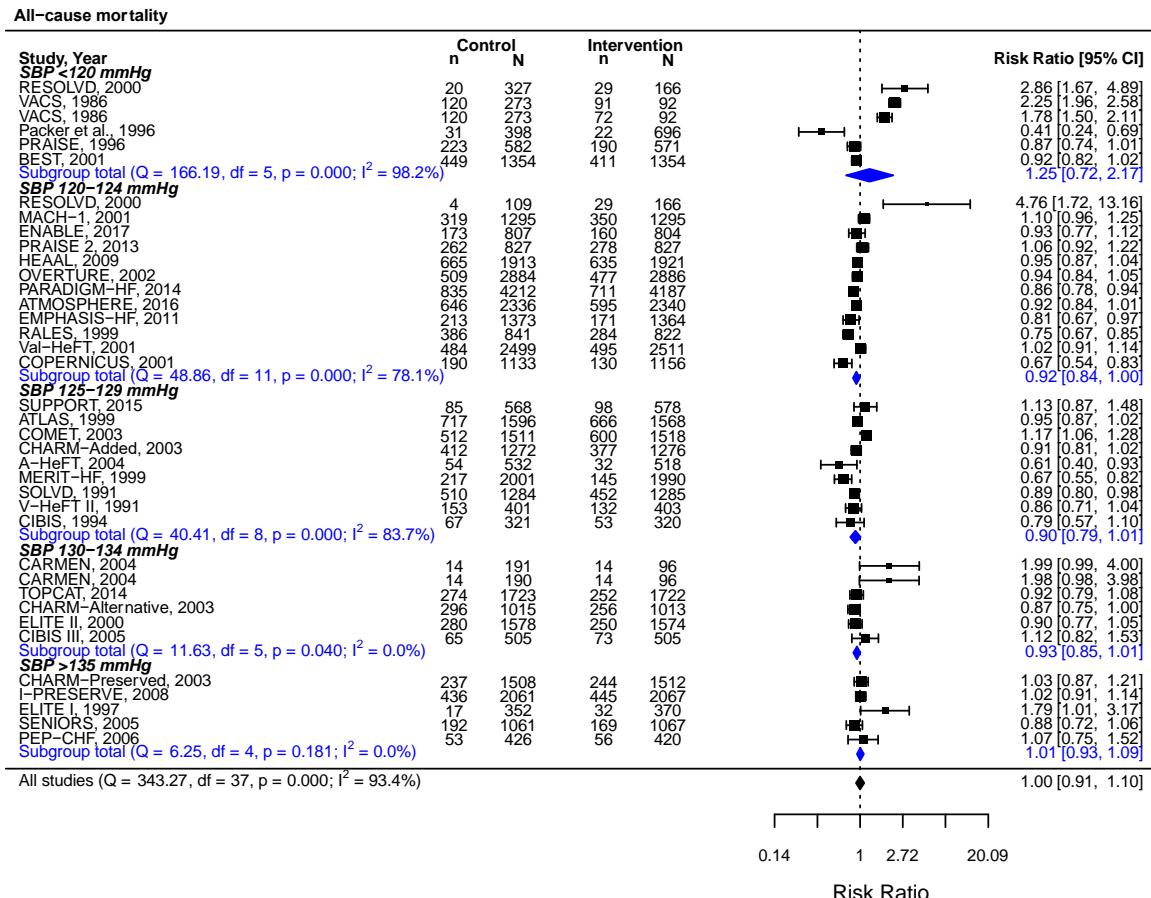

Risk ratios for heart failure (HF) hospitalisation were regressed against the mean difference in systolic blood pressure change between the intervention and control groups in each trial and stratified by left-ventricular ejection fraction using a 30% cut-off. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. SBP, systolic blood pressure

eFigure 7: Meta-regression of risk ratio for adverse events leading to treatment discontinuation according to the difference in systolic blood pressure between study groups stratified by left-ventricular ejection fraction

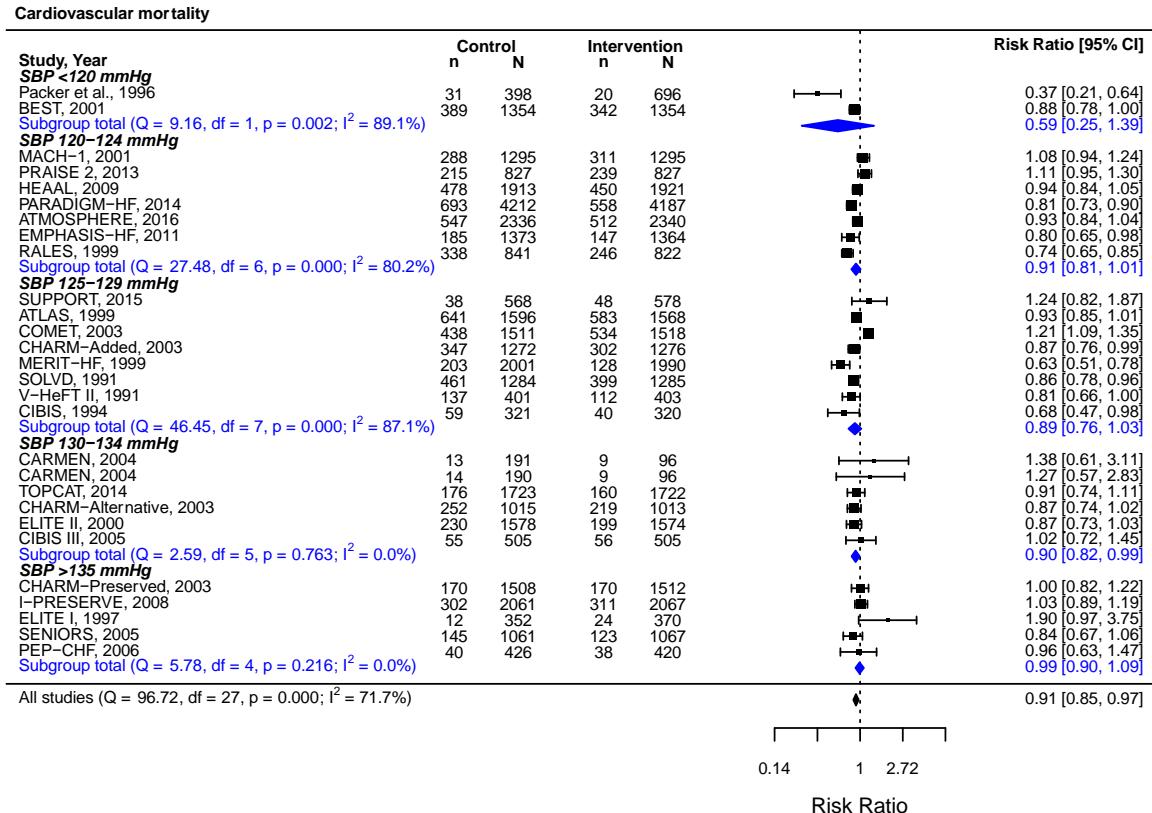

Risk ratios for adverse events leading to treatment discontinuation were regressed against the mean difference in systolic blood pressure change between the intervention and control groups in each trial and stratified by left-ventricular ejection fraction using a 30% cut-off. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. SBP, systolic blood pressure

eFigure 8: Meta-analysis of the effect of blood pressure-lowering treatment on all-cause mortality stratified by baseline systolic blood pressure

Risk ratios and 95% confidence intervals are displayed for all-cause mortality for each trial and strata of mean baseline systolic blood pressure aggregated at trial-level. Summary measures were calculated using random effects models with REML estimators. SBP, systolic blood pressure

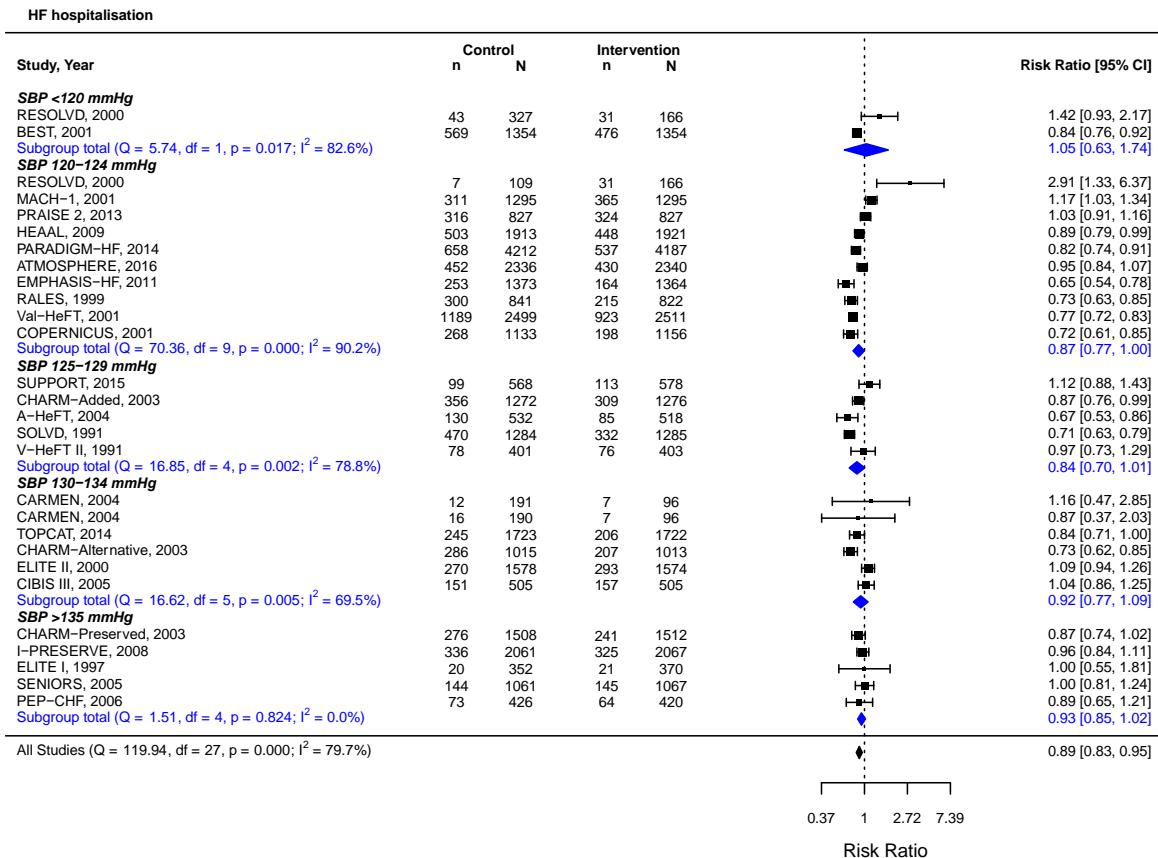

eFigure 9: Meta-analysis of the effect of blood pressure-lowering treatment on cardiovascular mortality stratified by baseline systolic blood pressure

Risk ratios and 95% confidence intervals are displayed for cardiovascular mortality for each trial and strata of mean baseline systolic blood pressure aggregated at trial-level. Summary measures were calculated using random effects models with REML estimators. n, number of events; N, total number of patients; SBP, systolic blood pressure

eFigure 10: Meta-analysis of the effect of blood pressure-lowering treatment on heart failure

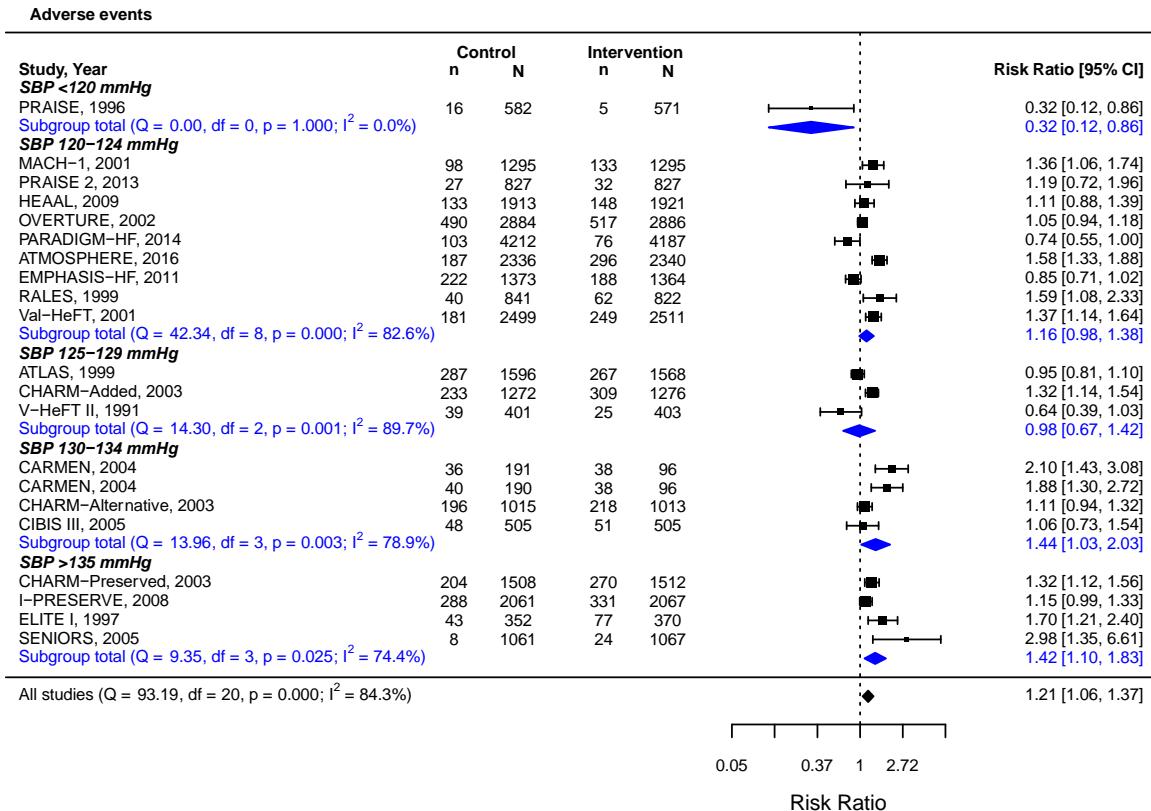

hospitalisation stratified by baseline systolic blood pressure

Risk ratios and 95% confidence intervals are displayed for heart failure (HF) hospitalisation for each trial and strata of mean baseline systolic blood pressure aggregated at trial-level. Summary measures were calculated using random effects models with REML estimators. n, number of events; N, total number of patients; SBP, systolic blood pressure

eFigure 11: Meta-analysis of the effect of blood pressure-lowering treatment on adverse events

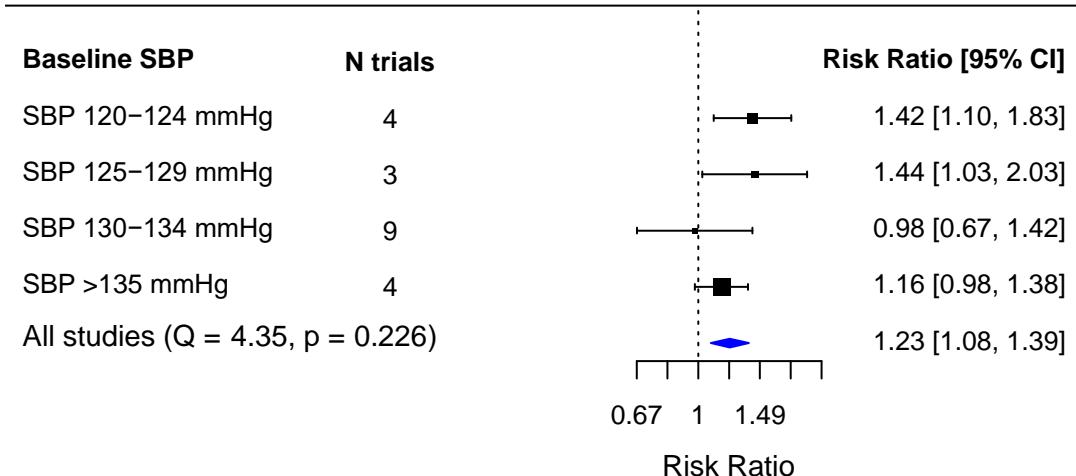

leading to treatment discontinuation stratified by baseline systolic blood pressure

Risk ratios and 95% confidence intervals are displayed for adverse events leading to treatment discontinuation for each trial and strata of mean baseline systolic blood pressure aggregated at trial-level. Summary measures were calculated using random effects models with REML estimators. n, number of events; N, total number of patients; SBP, systolic blood pressure

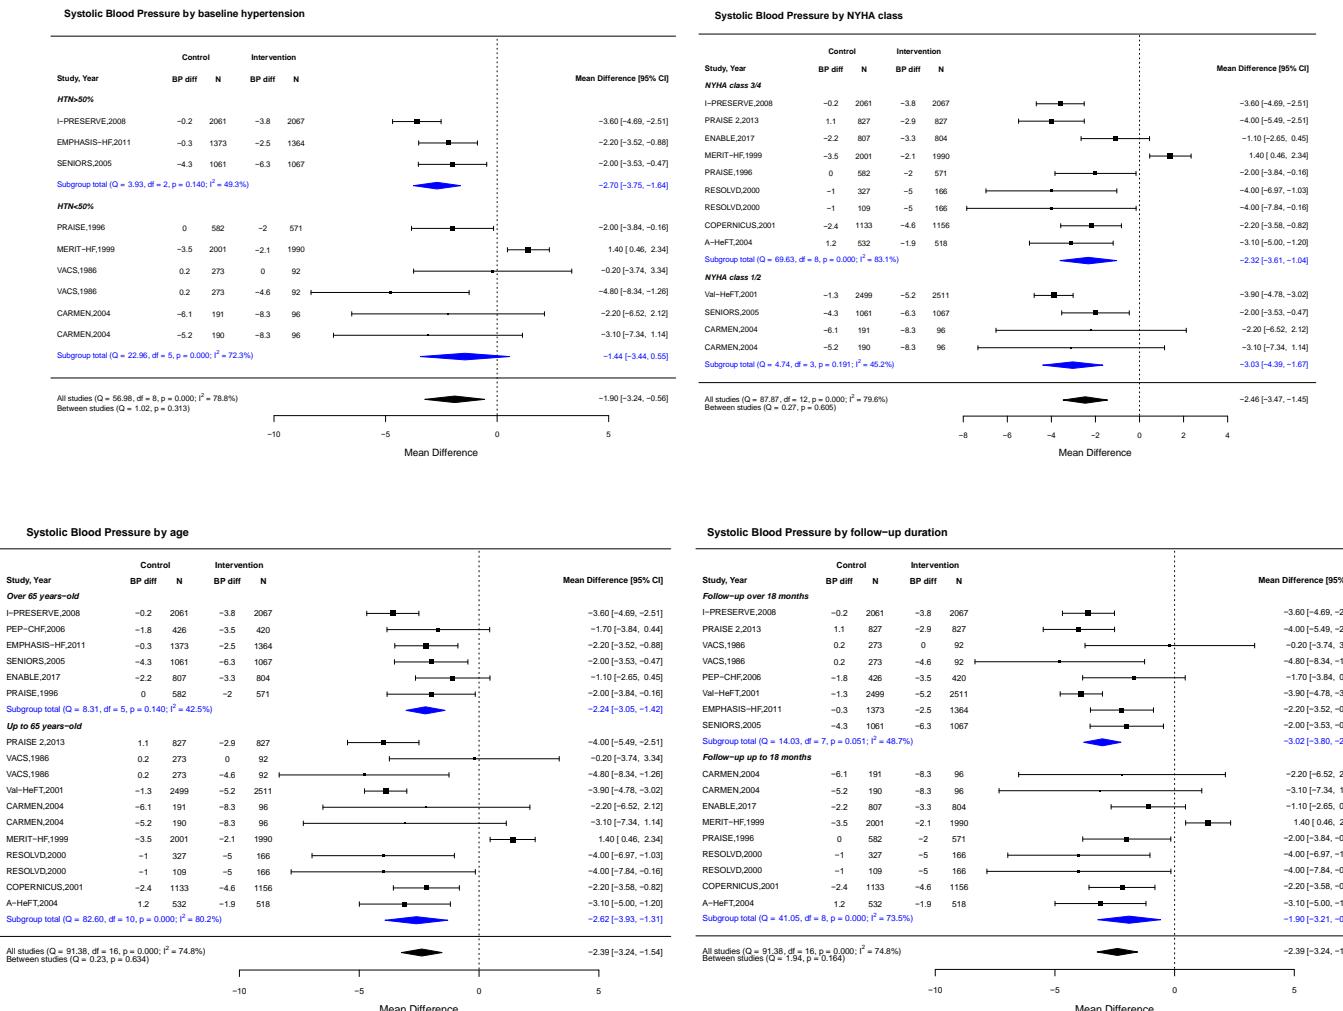

eFigure 12: Meta-analysis of the effect of blood pressure-lowering treatment on adverse events leading to treatment discontinuation stratified by baseline systolic blood pressure excluding the trial with systolic blood pressure below 120 mmHg

Adverse events

Risk ratios and 95% confidence intervals are displayed for adverse events leading to treatment discontinuation for each strata of mean baseline systolic blood pressure aggregated at trial-level, excluding the lowest stratum (<120 mmHg) which included only a single trial. This stratum had a significantly lower risk and when it was excluded the heterogeneity across strata of baseline systolic blood pressure was no longer statistically significant. Summary measures were calculated using random effects models with REML estimators. SBP, systolic blood pressure

eFigure 13: Meta-analysis of the effect of blood pressure-lowering treatment on systolic blood pressure stratified by hypertension at baseline, NYHA class at baseline, age and duration of follow-up.

Mean differences between the change in systolic blood pressure in the intervention group versus the control group are displayed for each trial and each subgroup. Top left: subgroup analysis for hypertension at baseline, with trials categorised as under or over 50% prevalence of baseline hypertension. Top right: subgroup analysis for NYHA class at baseline, with trials split into two categories according to the predominant NYHA class. Bottom left: subgroup analysis for age, with trials split according to patients' mean age. Bottom right: subgroup analysis for duration of follow-up with trials split into two categories according to mean duration of follow-up. Summary measures were calculated using random effects models with REML estimators. Negative values mean that the reduction in systolic blood pressure was greater in the intervention group and vice-versa. Only studies that compared active treatment with placebo were included. BP diff, difference between achieved and baseline systolic blood pressure; SBP, systolic blood pressure
